As mentioned earlier, a sense of independence, uniqueness, and self-esteem is seen by many Western personality theorists as fundamental to mental health. Psychoanalyst Erik Erikson included the appearance of personal identity and self-esteem as part of normal psychosocial development (see the chapter on human development). Middle-class Americans who fail to value and strive for independence, self-promotion, and unique personal achievement may be seen as displaying a personality disorder, some form of depression, or other psychological problems.

Do these ideas reflect universal truths about personality development or, rather, the influence of the cultures that generated them? It is certainly clear that people in many non-Western cultures develop personal orientations very different from those of North Americans and Europeans (Cross & Markus, 1999). In China and Japan, for example, an independent, unique self is not emphasized (Ho & Chiu, 1998). Children there are encouraged to develop and maintain harmonious relations with others and not to stand out from the crowd, lest they diminish someone else. In fact, the Japanese word for "different" (*tigau*) also means "wrong" (Kitayama & Markus, 1992). So whereas children in the United States hear that "the squeaky wheel gets the grease," Japanese children are warned that "the nail that stands out gets pounded down" (Markus & Kitayama, 1997). From a very young age, they are taught to be modest, to play down the value of personal contributions, and to appreciate the joy and value of group work (Kitayama & Markus, 1992).

In contrast to the *independent* self-system prevalent in individualist cultures (e.g., the United States, Great Britain, and Switzerland), countries characterized by a more collectivist orientation (e.g., Japan, China, Brazil, and Nigeria) promote an *interdependent* self-system through which people see themselves as a fraction of a whole, as an entity that has little or no meaningful definition without reference

Culture and Personality In individualist cultures, most children learn early that personal distinction is valued by parents, teachers, and peers. In cultures where collectivist values prevail, a strong sense of personal self-worth tends to be seen as a less important characteristic. In other words, the features of "normal" personality development vary from culture to culture.

to the group. These differences in self-systems may produce differences in the way people experience well-being. In the United States, a sense of personal well-being is typically associated with the feeling of *having positive attributes*, whereas in Japan and other Asian countries it is more likely to be associated with the feeling of *lacking negative attributes* (Eliot et al., 2001). Similarly, the results of studies conducted around the world indicate that in collectivist cultures, life satisfaction is associated with social approval and harmonious relations with others, whereas in individualist cultures, life satisfaction is associated with high self-esteem and feeling good about one's own life (Uchida et al., 2001).

Given that cultural factors shape notions about ideal personality development, it is important to evaluate various approaches to personality in terms of how well they apply to cultures other than the one in which they were developed (Cross & Markus, 1999). Their applicability to males and females must also be considered. Even within North American cultures, for example, there are gender differences in the development of self-esteem. Females tend to display an interdependent self-system, achieving their sense of self and self-esteem from attachments to others. By contrast, males' self-esteem tends to develop in relation to personal achievement, in a manner more in keeping with an independent self-system (Cross & Madson, 1997). Cross-gender and cross-cultural differences in the nature and determinants of a sense of self underscore the pervasive effects of gender and culture on the development of many aspects of human personality.

FOCUS ON RESEARCH METHODS

Longitudinal Studies of Temperament and Personality

Studying the development of personality over the life span requires *longitudinal* research, in which the same people are followed from infancy to adulthood so that their characteristics can be assessed at different points in their lives. A number of studies have used this longitudinal methodology to explore a variety of questions about changes in personality over time.

● What was the researchers' question?

The specific question addressed by Avshalom Caspi and his colleagues was whether the temperament children display at birth and in their early years predicts their personality and behavior as adults (Caspi, 2000; Caspi & Silva, 1995; Caspi et al., 1997; Caspi et al., 1995). As discussed in the chapter on human development, it is generally agreed that differences in temperament are influenced more by heredity than by the environment (Rowe, 1997).

● How did the researchers answer the question?

Caspi's research team studied all the children born in Dunedin, New Zealand, between April 1972 and March 1973—a total of about a thousand individuals. When the children were three years old, an examiner gave each of them a test of their cognitive abilities and motor skills and, using a three-point scale, rated their reactions to the testing situation. Some of the children exhibited explosive or uncontrolled behaviors; some interacted easily; some were withdrawn and unresponsive. (To avoid bias while making their ratings, the examiners were told nothing about the children's typical behavior outside of the testing room.) Based on these ratings, each child was placed into one of three temperament categories: *undercontrolled* (impulsive, restless, emotional), *overcontrolled* (shy, fearful, easily distracted), and *well-adjusted* (comfortable, friendly, calm, well-controlled). The children were reexamined at ages five, seven, and nine; but each time, a different person did the ratings, thus eliminating the possibility that an examiner's earlier

impressions might bias later ratings. Almost all correlations among the independent ratings made at various ages were positive and statistically significant, indicating that the temperament classifications were stable across time.

When the participants were eighteen years old, they completed a standard personality test. Finally, at the age of twenty-one, they were interviewed about the degree to which they engaged in risky and unhealthy behaviors such as excessive drinking, violent crime, unprotected sexual activity, and unsafe driving habits. To avoid bias, the interviewers were given no information about the participants' temperament when they were children or about their scores on the personality test.

● What did the researchers find?

Several significant differences were found among the average personality scores for the three temperament categories. For example, participants classified as "undercontrolled" at the age of three were more aggressive, alienated, negative, and hostile as adults than the other temperament groups. Further, people originally classified as "well-adjusted" were more forceful and decisive than were the people classified as "overcontrolled." And young adults who, as children, had been classified as "well-adjusted" tended to be effective individuals who were likely to assume leadership roles. These findings held true for males and females alike.

Caspi and his colleagues also found small but significant correlations between early temperament and health-risk and criminal behaviors (Caspi, 2000). For example, people classified as "overcontrolled" were more likely to avoid dangerous and exciting activities at the age of twenty-one than were those who had been classified as "undercontrolled." In fact, participants classified as "undercontrolled" were significantly more likely than either of the other groups to engage in risky behaviors and to have criminal records. The relationship between temperament in childhood and health-risk behaviors in young adulthood was not, however, a direct one. Statistical analyses revealed that temperament at age three affected personality at age eighteen, which in turn affected behavior patterns at age twenty-one.

● What do the results mean?

The results of Caspi's studies provide persuasive empirical support for a hypothesis long endorsed by personality psychologists: that relatively accurate predictions can be made about people's personality and behavior as adults on the basis of information about their temperament as children. However, the strength of these results should not be overstated. The relationships between temperament and personality, and between temperament and various problematic behaviors, though statistically significant, were also relatively modest. For example, not all the participants classified as "undercontrolled" at age three turned out to be aggressive or violent at age twenty-one. The implication is that personality is influenced and shaped by temperament, but not completely determined by it.

The results of these studies also confirm a point made in the chapter on health, stress, and coping—that personality plays a significant role in health. Specifically, personality characteristics predispose people to engage in behaviors that can affect their mental and physical health.

● What do we still need to know?

Caspi's research has revealed some continuity between temperament in childhood and personality in adulthood, but it also leaves some unanswered questions (Roberts & DelVecchio, 2000). For example, what factors underlie this continuity? The fact that there are individual differences in adult behavior within temperament groups shows that a child is not simply biologically programmed to exhibit certain personality traits later. One explanation offered by Caspi and his colleagues draws heavily on social-cognitive theories, particularly on Bandura's notion of *reciprocal determinism*. These researchers believe that long-term consistencies in behavior result from the mutual influence that temperament and environmental events have on one another. They propose, for example, that people tend to put themselves in situations that reinforce their temperament. So "undercontrolled" people might

choose to spend time with people who accept and even encourage rude or impolite behavior. And when such behavior brings negative reactions, the world seems that much more hostile, and they become even more aggressive and negative. Caspi and his colleagues see the results of their studies as evidence that this process of mutual influence between personality and situations can continue over a lifetime (Caspi & Roberts, 1999).

Assessing Personality

Psychologists describe people's personalities using information from four main sources (Ozer, 1999): *life outcomes* (such as level of education, income, or marital status), *situational tests* (laboratory measurements of behavioral, emotional, and physiological reactions to conflict, frustration, and the like), *observer ratings* (judgments about a person made by family or friends), and *self-reports* (responses to interviews and personality tests). The data gathered through these methods are used for many purposes, including diagnosing psychological disorders, predicting dangerousness, selecting new employees, and even choosing astronaut candidates best suited to space travel (Butcher & Rouse, 1996; Groth-Marnat, 1997; Meyer et al., 2001; Nietzel et al., 2003).

Observer ratings and situational tests allow direct assessment of many aspects of behavior, including how often, how effectively, and how consistently various actions occur. *Interviews* provide a way to gather information about personality from the person's own point of view. Some interviews are *open-ended*, meaning that questions are tailored to the intellectual level, emotional state, and special needs of the person being interviewed. Others are *structured*, meaning that the interviewer asks a fixed set of questions about specific topics in a particular order. Structured interviews are routinely used in personality research because they are sure to cover matters of special interest to the researcher.

Personality tests offer a way of gathering self-report information that is more standardized and economical than interviews. To be useful, however, a personality test must be reliable and valid. As described in the chapter on cognitive abilities, reliability refers to how stable or consistent the results of a test are; validity reflects the degree to which a test measures what it is intended to measure and leads to correct inferences about people. The many personality tests available today are traditionally classified as either *objective* or *projective*.

Objective Personality Tests

Objective personality tests contain clearly stated items that relate to a person's thoughts, feelings, or behavior (such as "Do you like parties?"). The most common kind of objective personality test is similar in format to the multiple-choice or true-false examinations used in many classrooms. Like those exams, self-report personality tests can be administered to many people at the same time; they can also be machine scored. However, whereas there is only one correct answer for each item on a classroom exam, the "correct" answers to an objective personality test depend on who is taking it. Each person is asked to respond in a way that best describes him or her.

Ultimately, the person's responses to the objective test's items are combined into a score. That score can be used to draw conclusions about the respondent's personality, but only after it has been compared with the responses of thousands of other people who have taken the same test. For example, before interpreting your score of "77" on a self-report test of extraversion, a psychologist would compare the score with *norms*, or average scores from other individuals of your age and gender.

objective personality tests Personality tests containing direct, unambiguous items relating to the individual being assessed.

table 14.3

Sample Summary of Results from the NEO-PI-R

Compared with the responses of other people, your responses suggest that you can be described as:

- | | | |
|--|---|---|
| <input type="checkbox"/> Sensitive, emotional, and prone to experience feelings that are upsetting. | <input checked="" type="checkbox"/> Generally calm and able to deal with stress, but you sometimes experience feelings of guilt, anger, or sadness. | <input type="checkbox"/> Secure, hardy, and generally relaxed even under stressful conditions. |
| <input type="checkbox"/> Extraverted, outgoing, active, and high-spirited. You prefer to be around people most of the time. | <input type="checkbox"/> Moderate in activity and enthusiasm. You enjoy the company of others, but you also value privacy. | <input checked="" type="checkbox"/> Introverted, reserved, and serious. You prefer to be alone or with a few close friends. |
| <input type="checkbox"/> Open to new experiences. You have broad interests and are very imaginative. | <input type="checkbox"/> Practical but willing to consider new ways of doing things. You seek a balance between the old and the new. | <input checked="" type="checkbox"/> Down-to-earth, practical, traditional, and pretty much set in your ways. |
| <input type="checkbox"/> Compassionate, good-natured, and eager to cooperate and avoid conflict. | <input checked="" type="checkbox"/> Generally warm, trusting, and agreeable, but you can sometimes be stubborn and competitive. | <input type="checkbox"/> Hardheaded, skeptical, proud, and competitive. You tend to express your anger directly. |
| <input checked="" type="checkbox"/> Conscientious and well organized. You have high standards and always strive to achieve your goals. | <input type="checkbox"/> Dependable and moderately well organized. You generally have clear goals but are able to set your work aside. | <input type="checkbox"/> Easygoing, not very well organized, and sometimes careless. You prefer not to make plans. |

The NEO-PI-R assesses the big-five personality dimensions. In this example of the results a respondent might receive, the five factors scored are, from the top row to the bottom row, neuroticism, extraversion, openness, agreeableness, and conscientiousness. Because people with different NEO profiles tend to have different psychological problems, this test has been used to aid in the diagnosis of personality disorders (Trull & Sher, 1994).

Only if you were well above these averages would you be considered unusually extraverted.

Some self-report tests focus on one personality trait, such as optimism (Scheier et al., 1989); others measure a set of related traits, such as empathy and social responsibility (Penner, in press). Still others measure the strength of a wider variety of traits to reveal general psychological functioning. For example, the *Neuroticism Extraversion Openness Personality Inventory, Revised*, or NEO-PI-R (Costa & McCrae, 1992), is designed to measure the big-five personality traits described earlier. Table 14.3 shows how the test's results are presented. One innovative feature of the NEO-PI-R is its "private" and "public" versions. The first version asks for the respondent's self-assessment; the second version asks a person who knows the respondent to rate him or her on various dimensions. Personality descriptions derived from the two versions are often quite similar, but discrepancies may indicate problems. For example, if a person's self-ratings are substantially different from those of a spouse, marital problems may be indicated; in addition, the nature of the discrepancies could suggest a focus for marital therapy.

The NEO-PI-R is quite reliable (Viswesvaran & Ones, 2000), and people's scores on its various scales have been successfully used to predict a number of criteria, including performance on specific jobs and overall career success (Barrick & Mount, 1991; Siebert & Kraimer, 2001), social status (Anderson et al., 2001), and the likelihood of continued criminal behavior (Clower & Bothwell, 2001).

When the goal of personality testing is to diagnose psychological disorders, the most commonly used objective test is the *Minnesota Multiphasic Personality Inventory*, or the MMPI (Butcher & Rouse, 1996). This 566-item true-false test was originally developed during the 1930s at the University of Minnesota by Starke

figure 14.6**The MMPI: Clinical Scales and Sample Profiles**

A score of 50 on the clinical scales of the MMPI is average. Scores at or above 65 mean that the person's responses on that scale are more extreme than at least 95 percent of the normal population. The green line represents the profile of Kenneth Bianchi, the infamous "Hillside Strangler" who murdered thirteen women in the late 1970s. His profile would be interpreted as characteristic of a shallow person with poor self-control and little personal insight who is sexually pre-occupied and unable to reveal himself to others. The profile in purple comes from a more normal man, but it is characteristic of someone who is self-centered, passive, and unwilling to accept personal responsibility for his behavior, and who, when under stress, complains of numerous vague physical symptoms.

The clinical scales abbreviated in the figure are as follows:

1. Hypochondriasis (Hs; concern with bodily functions and symptoms).
2. Depression (D; pessimism, hopelessness, slowed thinking).
3. Hysteria (Hy; use of physical or mental symptoms to avoid problems).
4. Psychopathic deviate (Pd; disregard for social customs, emotional shallowness).
5. Masculinity/femininity (Mf; interests associated with a particular gender).
6. Paranoia (Pa; delusions, suspiciousness).
7. Psychasthenia (Pt; worry, guilt, anxiety).
8. Schizophrenia (Sc; bizarre thoughts and perceptions).
9. Hypomania (Ma; overactivity, excitement, impulsiveness).
0. Social introversion (Si; shy, insecure).

Hathaway and J. C. McKinley. It has subsequently been revised and updated to become the MMPI-2 (National Computer Systems, 1992). The MMPI's items are organized into ten *clinical scales*. These are groups of items that, in earlier research, had drawn a characteristic pattern of responses only from people who displayed particular psychological disorders or personality characteristics (see Figure 14.6).

Interpreting the MMPI is largely a matter of using computer programs to compare respondents' profiles—such as those shown in Figure 14.6—to the profiles of people already known to display certain personality characteristics. Respondents are presumed to share characteristics with the group whose profile most closely resembles theirs. So whereas a very high score on one scale, such as depression, might indicate a problem in the dimension measured by that scale, MMPI interpretation usually focuses on the overall *pattern* in the clinical scales—particularly on the combination of two or three scales on which a person has unusually high scores.

There is considerable evidence for the reliability and validity of MMPI clinical scales, but even the latest editions of the test are far from perfect measurement tools (Groth-Marnat, 1997; McIntire & Miller, 2000). The validity of MMPI interpretations may be particularly suspect when—because of cultural factors—the perceptions, values, and experiences of a respondent are notably different from those of the test developers and the people to whom the respondent's results are compared. A profile that looks typical of people with a certain disorder might reflect the culture-specific way the respondent interpreted the test items, not a mental problem (Groth-Marnat, 1997). Even though the MMPI-2 uses comparison norms that

figure 14.7

Interpretations of a Draw-a-Person Test

These drawings were done by an eighteen-year-old male who had been caught stealing a television set. A psychologist interpreted the muscular figure as the young man's attempt to boast of masculine prowess, but saw the muscles' "puffy softness" as suggesting feelings of inadequacy. The drawing of the baby-like figure was seen to reveal vulnerability, dependency, and a need for affection. Appealing as these interpretations may be, research does not generally support the value of projective tests in personality assessment (Lilienfeld, Wood, & Garb, 2000).

Source: Hammer (1968).

represent a more culturally diverse population than did those of the original MMPI, psychologists must remain cautious when interpreting profiles of people who are members of minority subcultures.

Projective Personality Tests

Unlike objective tests, **projective personality tests** contain relatively unstructured stimuli, such as inkblots, which can be perceived in many ways. Proponents of projective tests tend to take a psychodynamic approach to personality. They believe that people's responses to the tests' ambiguous stimuli are guided by unconscious needs, motives, fantasies, conflicts, thoughts, and other hidden aspects of personality. Some projective tests ask people to draw items such as a house, a person, or a tree (see Figure 14.7); to fill in the missing parts of incomplete pictures or sentences; or to say what they associate with a particular word. Projective techniques are sometimes used in basic personality research, but they are far more popular among clinical psychologists, who use them in the assessment of psychological disorders (Lilienfeld, Wood, & Garb, 2000).

One prominent projective test, developed by Henry Murray and Christina Morgan, is called the *Thematic Apperception Test*, or TAT. As described in the chapter on motivation and emotion, the TAT is used to measure need for achievement (see Figure 11.7). It is also used to assess other needs (e.g., needs for power or affiliation) that Murray and Morgan saw as the basis for personality. Another widely used projective test, the *Rorschach Inkblot Test*, asks people to say what they see in a series of inkblots (see Figure 14.8).

Advocates claim that the ambiguity of projective test items makes it difficult for respondents to detect what is being measured and what the "best" answers would be. They argue, therefore, that these tests can measure aggressive and sexual impulses and other personality features that people might otherwise be able to hide. However, in comparison to objective-test results, responses to projective tests are also much more difficult to translate into numerical scores for scientific analysis. In an effort to reduce the subjectivity involved in projective-test interpretation, some psychologists

figure 14.8

TRY THIS

The Rorschach Inkblot Test

The Rorschach test consists of ten patterns—some in color, others in black and white. The respondent is asked to tell what the blot might be and then to explain why. This pattern is similar to one of those in the Rorschach test. What do you see? Most scoring methods focus on (1) what part of the blot the person responds to; (2) what details, colors, or other features appear to determine each response; (3) the content of responses (such as seeing animals, maps, or body parts); and (4) the popularity or commonness of the responses.

in review Personality Tests

Type of Test	Characteristics	Advantages	Disadvantages
Objective	Asks direct questions about a person; quantitatively scored	Efficiency, standardization	Subject to deliberate distortion
Projective	Unstructured stimuli create maximum freedom of response; scoring is subjective, though some objective methods exist	"Correct" answers not obvious; designed to tap unconscious impulses; flexible use	Reliability and validity lower than those of objective tests

have developed more structured—and thus potentially more reliable—scoring systems for instruments such as the Rorschach (Erdberg, 1990; Exner & Ona, 1995). There are in fact specific instances—as in studies assessing achievement motivation with the TAT—where projective tests show acceptable reliability and validity (Schultheiss & Brunstein, 2001), but overall, projective personality tests are substantially less reliable and valid than objective tests (Garb, Florio, & Grove, 1998; Lilienfeld, Wood, & Garb, 2000). Because of their generally low predictive validity, projective tests often add little information beyond what might be inferred from life outcome data, interviews, and objective personality tests (Lilienfeld, Wood, & Garb, 2000). ("In Review: Personality Tests" summarizes the characteristics of objective and projective tests, along with some of their advantages and disadvantages.)

Personality Tests and Employee Selection

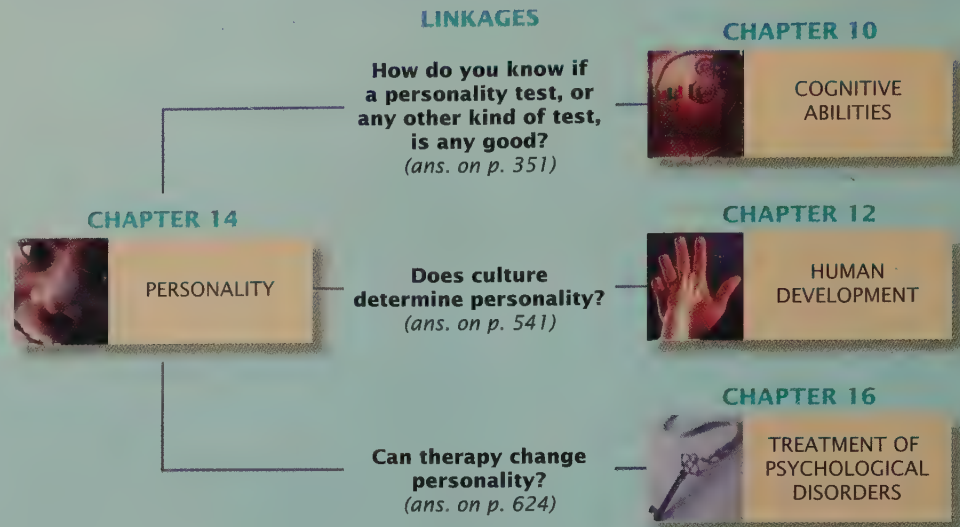

How good are personality tests at selecting people for jobs? Most industrial/organizational psychologists believe these tests are valuable tools in the selection of good employees. The MMPI (and even some projective tests) are occasionally employed for such purposes (e.g., Bartol, 1991), but the majority of personality tests used by large organizations are those that measure the big-five personality dimensions or related characteristics (Borman, Hanson, & Wedge, 1997; Costa, 2001). Several researchers have found significant relationships between scores on these characteristics and measures of overall job performance and effective leadership (Barrick & Mount, 1991; Ones & Viswesvaran, 1996; Silverthorne, 2001). A more general review of studies involving thousands of people has shown that objective personality tests are of value in helping businesses reduce thefts and other disruptive employee behaviors (Ones & Viswesvaran, 2001).

Still, personality tests are far from perfect predictors of behavior, and as noted earlier, they sometimes lead to incorrect predictions. Many tests measure traits that may be too general to predict specific aspects of job performance (Furnham 2001), and in any case, personality characteristics may influence performance in some job situations but not in others (Ones & Viswesvaran, 2001). Further, some employees see personality tests as an invasion of their privacy. They worry also that test results in their personnel files might later be misinterpreted and hurt their chances for promotion or for employment by other companies. Lawsuits have resulted in a ban on the use of personality tests in the selection of U.S. federal employees. Concerns about privacy and other issues surrounding personality testing have also led the American Psychological Association and related organizations to publish ethical standards relating to procedures for the development, dissemination, and use of all psychological tests (American Educational Research Association, American Psychological Association, and National Council on Measurement in Education, 1999; American Psychological Association, 1992b). The goal is not only to improve the reliability and validity of tests but also to ensure that their results are properly used and do not infringe on individuals' rights (Turner et al., 2001).

projective personality tests Personality tests made up of unstructured stimuli that can be perceived and responded to in many ways.

LINKAGES

As noted in the chapter on introducing psychology, all of psychology's subfields are related to one another. Our discussion of cultural factors and personality illustrates just one way in which the topic of this chapter, personality, is linked to the subfield of developmental psychology (which is the focus of the chapter on human development). The Linkages diagram shows ties to two other subfields as well, and there are many more ties throughout the book. Looking for linkages among subfields will help you see how they all fit together and help you better appreciate the big picture that is psychology.

SUMMARY

Personality refers to the unique pattern of psychological and behavioral characteristics by which each person can be compared and contrasted with other people. The four main theoretical approaches to personality are the psychodynamic, trait, social-cognitive, and humanistic approaches.

The Psychodynamic Approach

The *psychodynamic approach*, first proposed by Sigmund Freud, assumes that personality arises out of the interplay of various unconscious psychological processes.

The Structure and Development of Personality

Freud believed that personality has three components—the *id*, which has a reservoir of *libido* and operates according to the *pleasure principle*; the *ego*, which operates according to the *reality principle*; and the *superego*, which internalizes society's rules and values. The ego uses *defense mechanisms* to prevent unconscious conflicts among these components from becoming conscious and causing anxiety or guilt. Freud proposed that the focus of conflict changes as the child passes through *psychosexual stages* of development, called the *oral stage*, the *anal stage*, the *phallic stage* (during which the *Oedipus complex* or the *Electra complex* arises), the *latency period*, and the *genital stage*.

Variations on Freud's Personality Theory

Many of Freud's early followers developed new theories that differed from his. Among these theorists were Carl Jung, Alfred Adler, and Karen Horney. These and other theorists tended to downplay the role of instincts and the unconscious, emphasizing instead the importance of conscious processes, ego functions, and social and cultural factors. Horney also challenged the male-oriented nature of Freud's original theory.

Contemporary Psychodynamic Theories

Current psychodynamic theories are derived from the neo-Freudians' emphasis on family and social relationships. According to object relations theorists, personality development depends mainly on the nature of early interactions between individuals and their caregivers (objects).

Evaluation of the Psychodynamic Approach

Despite evidence in support of some psychodynamic concepts and recent attempts to test psychodynamic theories more precisely and objectively, critics still fault the approach for its lack of a scientific base and for its view of human behavior as driven by unmeasurable forces.

The Trait Approach

The *trait approach* to personality assumes that personality is made up of stable internal characteristics that appear at varying strengths in different people and guide their thoughts, feelings, and behavior.

Allport's Trait Theory

Gordon Allport believed that personality is created by a small set of central traits and a larger number of secondary traits in each individual. He analyzed language to try to identify those traits, thus laying the foundation for modern research on personality traits.

The Big-Five Model of Personality

Building on the work of Allport and Raymond Cattell, contemporary researchers have used factor analysis to identify five basic dimensions of personality, collectively referred to as the

big-five model, or five-factor model. These dimensions, which have been found in many different cultures.

Biological Trait Theories

Hans Eysenck believed that differences in nervous system arousal are responsible for differences in core dimensions of personality, especially introversion-extraversion and emotionality-stability. Newer biological theories have largely supplanted Eysenck's theory, and they suggest instead that these differences are due to biological differences in the sensitivity of brain systems involved with responsiveness to rewards and to punishments.

Evaluation of the Trait Approach

The trait approach has been criticized for being better at describing personality than at explaining it, for failing to consider mechanisms that motivate behavior, and for underemphasizing the role of situational factors. Nevertheless, the trait approach—particularly the big-five model—currently dominates the field of personality.

The Social-Cognitive Approach

The *social-cognitive approach* to personality focuses on the thoughts and feelings that influence people's behavior and assumes that personality is a label that summarizes the unique patterns of thinking and behavior that a person learns in the social world.

Roots of the Social-Cognitive Approach

With roots in research on classical and operant conditioning (including Skinner's *functional analysis* of behavior), the social-cognitive approach has expanded on traditional behavioral approaches by emphasizing the role of cognitive factors, such as observational learning, in personality development.

Prominent Social-Cognitive Theories

Julian Rotter's theory focuses on cognitive expectancies that guide behavior, and it generated interest in assessing general beliefs about whether rewards occur because of personal efforts (internal control) or chance (external control). Albert Bandura believes that personality develops largely through cognitively mediated learning, including observational learning. He sees personality as reciprocally determined by interactions among cognition, environmental stimuli, and behavior. *Perceived self-efficacy*—the belief in one's ability to accomplish a specific task—is an important determinant of behavior. Walter Mischel emphasizes the importance of cognitive person variables and their interactions with the characteristics of particular situations in determining behavior. According to Mischel, we must look at both cognitive person variables and situational variables in order to understand human consistencies and inconsistencies.

Evaluation of the Social-Cognitive Approach

The social-cognitive approach has gained wide acceptance because it has merged theories from behavioral and cognitive psychology and used them to explain a wide range of important social behaviors. However, the approach has been criticized for

failing to provide one coherent theory of personality and failing to capture the complexity, richness, and uniqueness of human personalities.

The Humanistic Approach

The *humanistic approach* to personality is based on the assumption that people are primarily motivated by a desire to fulfill their natural potential in a uniquely perceived version of reality. So to understand a person, you have to understand the person's view of the world, which serves as the basis for personality and guides behavior.

Prominent Humanistic Theories

Carl Rogers believed that personality development is driven by an innate *actualizing tendency*, but also that one's *self-concept* is shaped by social evaluations. He proposed that when people are free from the effects of *conditions of worth*, they will be psychologically healthy and achieve self-actualization. Abraham Maslow saw self-actualization as the highest in a hierarchy of needs. Personality development is healthiest, he said, when people have a *growth orientation* rather than a *deficiency orientation*.

Evaluation of the Humanistic Approach

Although it has a large following, the humanistic approach is faulted for being too idealistic, for failing to explain personality development, for being vague and unscientific, and for underplaying cultural differences in "ideal" personalities.

Assessing Personality

The information used in personality assessment comes from four main sources: life outcomes, situational tests, observer ratings, and self-reports. To be useful, personality assessments must be both reliable and valid.

Objective Personality Tests

Objective personality tests contain clearly worded items relating to the individual being assessed; their scores can be compared with group norms. The MMPI and the NEO-PI-R are examples of objective tests.

Projective Personality Tests

Based on psychodynamic theories, *projective personality tests* present ambiguous stimuli in an attempt to tap unconscious personality characteristics. Two popular projective tests are the TAT and the Rorschach Inkblot Test. In general, projective personality tests are less reliable and valid than objective personality tests.

Personality Tests and Employee Selection

Objective personality tests are often used to identify the people best suited for certain occupations. Although such tests can be helpful in this regard, those who use them must be aware of the tests' limitations and take care not to violate the rights of test respondents.

Summary

During his first year at college, Mark began to worry about news stories describing the deadly diseases resulting from hantavirus, “flesh-eating” strep bacteria, and HIV. He took a blood test for HIV, the virus that causes AIDS, and was relieved when it showed no infection. But then he wondered if he might have contracted HIV after he took the test. Library research and a call to an AIDS hotline revealed that HIV antibodies may not appear until six months after infection. Mark took another blood test, also negative, but he still worried when he learned that the AIDS virus can live outside of the human body for anywhere from ten minutes to several hours or even days. He also read that no one can explain why hantavirus appears in new places or why some rare forms of bacteria cause deadly lesions.

Given this uncertainty, Mark concluded that HIV, hantavirus, and “flesh-eating” strep bacteria can live indefinitely outside of the body and could therefore be anywhere and everywhere. He decided that the only safe course was not just sexual abstinence but absolute cleanliness. Mark began to scrub himself whenever he touched doorknobs, money, walls, floors—anything. People with HIV or other deadly viruses or bacteria, he thought, could have touched these things, or they might have bled on the street and he might have tracked their infected blood into his car and house and bathroom. Eventually he felt the need to scrub everything around him up to forty times in each direction; it took him several exhausting hours just to shower and dress. He washed the shower knobs before touching them and, once in the shower, felt that he had to wash his body in cycles of thirteen strokes. If his feet touched the bare floor, he had to wash them again before putting on his underwear to ensure that his feet would not contaminate the fabric. He was sure that his hands, rubbed raw from constant washing, were especially susceptible to infection, so he wore gloves at all times except in the summer, when he wrapped his fingers in flesh-colored bandages. The process of protecting himself from infection was wearing him out and severely restricting his activities; he could not go anywhere without first considering the risk of infection.

Mark’s case provides an example of someone who suffers from a psychological disorder, also called a *mental disorder* or *psychopathology*. **Psychopathology** is generally defined as patterns of thought, emotion, and behavior that result in personal distress or a significant impairment in a person’s social or occupational functioning. Identifying psychopathology, then, is a social as well as a personal matter, and deciding who “has it” depends in part on how a particular culture defines *normal* and *abnormal* (Castillo, 1997).

In Western cultures, these terms are defined in such a way that a large number of people can be said to display some form of psychological disorder. Surveys reveal that in any given year in the United States alone, about 57 million people, or about 30 percent of the adult population, have displayed some form of mental disorder, and that as many as 48 percent have experienced a disorder at some point in their lives (Kessler et al., 1996; Regier et al., 1993a, 1993b; Robins & Regier, 1991; U.S. Surgeon General, 1999; see Figure 15.1). In addition, about 20 percent of U.S. children display significant mental disorders in any given year (Costello et al., 1988; U.S. Surgeon General, 1999). These overall rates of mental disorder are found, with only minor variations, in all segments of U.S. society, including males and females in all ethnic groups (Peterson et al., 1993). Bear in mind that the actual rates may be higher than the percentages just cited, because major survey studies have examined fewer than half of all known psychological disorders.

These psychological disorders are enormously costly in terms of human suffering, wasted potential, economic burden, and lost resources (Druss, Rosenheck, & Sledge, 2000; Lopez & Murray, 1998; Lyons & McLoughlin, 2001). In this chapter we discuss how abnormality is defined and classified. We also describe the major categories of psychological disorders, along with some of their possible causes, and we examine legal issues related to psychopathology.

psychopathology Patterns of thinking, feeling, and behaving that are maladaptive, disruptive, or uncomfortable for the person affected or for those with whom he or she comes in contact.

figure 15.1
Prevalence of Specific Psychological Disorders

Several large-scale surveys of adults throughout the United States revealed that about 30 percent of them experience some form of mental disorder in any given year, and that almost half of them have displayed a disorder at some time in life. The data shown here summarize these findings by category of disorder. The figures are somewhat lower if only the more severe cases are counted (Narrow et al., 2002), but these disorders still pose major problems for society. Worldwide, over 400 million people suffer from some form of psychological disorder (World Health Organization, 2001).

Defining Psychological Disorders

A woman’s husband dies, and in her grief she stays in bed all day, weeping, refusing to eat, at times holding “conversations” with him. In India, a Hindu holy man on a pilgrimage rolls along the ground across a thousand miles of deserts and mountains, pelted by monsoon rains, until he reaches the sacred place he seeks. Eight percent of adults in the United States say they have seen a UFO (CNN/Time, 1997), and hundreds of people around the world claim to have been abducted by space aliens (Appelle et al., 2000). These examples and countless others raise the question of where to draw the line between normality and abnormality, between eccentricity and mental disorder (Kanner, 1995).

Is This Man Abnormal? This photo might have made you cringe. But whether unusual individuals are labeled “abnormal” and perhaps given treatment for psychological disorder depends on a number of factors, including how *abnormality* is defined by the culture in which they live, who is most directly affected by their behavior, and how much distress they suffer or cause.

What Is Abnormal?

There are several criteria for judging whether people’s thinking, emotions, or behaviors are abnormal. Each criterion has value, but also some flaws.

Infrequency If we define *normality* as what most people do, an obvious criterion for abnormality is *statistical infrequency*—that which is unusual. By this criterion, the few people who believe that space aliens are stealing their thoughts would be judged abnormal; the many people who worry about becoming victims of crime or terrorism would not. Statistical infrequency alone is a poor criterion for abnormality, however, because some characteristics that appear only rarely—creative genius, extraordinary language skills, or world-class athletic ability, for example—may be highly valued. Further, because this definition implies that conformity with the majority is normal, equating rarity with abnormality can result in the oppression of nonconformists who express minority views in a society—as is reportedly occurring in China, for example (Eckholm, 2001). Finally, just how rare must a behavior be to warrant the designation of “abnormal”? The dividing line is not easy to locate.

Norm Violation Abnormality can also be defined in terms of whether someone violates social norms—the cultural rules that tell us how we should and should not behave in various situations, especially in relation to others (see the chapter on social influence). According to this *norm violation* criterion, when

people behave in ways that are bizarre, unusual, or disturbing enough to violate social norms, they may be described as abnormal.

Like the other criteria, however, norm violation alone is an inadequate measure of abnormality. For one thing, some norm violations are better characterized as eccentric or illegal than as abnormal (Weeks & Weeks, 1995). People who bathe infrequently or who stand too close during conversation violate social norms, but are they abnormal or merely annoying? Further, whose norms are we talking about? Social norms vary across cultures, subcultures, and historical eras, so behaviors that qualify as abnormal in one part of the world might be perfectly acceptable elsewhere.

Personal Suffering Another criterion for abnormality is *personal suffering*. In fact, experiencing distress is the criterion that people often use in deciding that their psychological problems are severe enough to require treatment. But personal suffering alone is an inadequate criterion for abnormality because it does not take into account the fact that some people's excessive distress may result from events or behaviors that are not pathological (e.g., the death of a loved one, or being homosexual). Conversely, people who display psychological disorders may experience little or no distress if the disorders have impaired their ability to recognize how maladaptive their behavior is. Those who sexually abuse children, for example, create far more distress in victims and their families than they suffer themselves.

Behavior in Context: A Practical Approach

Because no single criterion is entirely adequate for identifying abnormality, mental health practitioners and researchers tend to adopt a *practical approach* that combines aspects of all the criteria we've discussed. They consider the *content* of behavior (i.e., what the person does); the sociocultural *context* in which the person's behavior occurs; and the *consequences* of the behavior for that person, as well as for others. This practical approach pays special attention to whether a person's thoughts, behavior, or emotions cause **impaired functioning**—that is, difficulty in fulfilling appropriate and expected family, social, and work-related roles (U.S. Surgeon General, 1999; Wakefield, 1999).

What is "appropriate" and "expected" depends on age, gender, and culture, as well as on the particular situation and historical era in which people find themselves. For example, the same short attention span that is considered normal in a two-year-old would be considered inappropriate and problematic in an adult. There are gender-specific norms as well. In some countries, for example, it is more appropriate for women than for men to display emotion. Kisses, tears of happiness, and long embraces are common when women greet each other after a long absence; men tend to simply shake hands or, at most, hug briefly. Because of cultural differences, hearing a dead relative's voice calling from the afterlife would be more acceptable in certain North American Indian tribes than among, say, the families of suburban Toronto. Situational factors are important, too. Falling to the floor and "speaking in tongues" is considered appropriate, even desirable, during the worship services of certain religious groups, but the same behavior would be inappropriate, and a sign of disorder, in a college classroom. Finally, judgments about behavior are shaped by changes in social trends and cultural values. For example, the American Psychiatric Association once listed homosexuality as a mental disorder but dropped this category from its *Diagnostic and Statistical Manual of Mental Disorders* in 1973. In taking this step, it was responding to changing views of homosexuality that were prompted in part by the political and educational efforts of gay and lesbian rights groups.

In summary, it is difficult, and probably impossible, to define a specific set of behaviors that everyone, everywhere, will agree constitutes abnormality (Lilienfeld & Marino, 1999; Wakefield, 1999). The practical approach defines abnormality as including those patterns of thought, behavior, and emotional reaction that significantly impair people's functioning within their culture (Wakefield, 1992).

LINKAGES (a link to Social Influence)

impaired functioning Difficulty in fulfilling appropriate and expected family, social, and work-related roles.

Explaining Psychological Disorders

Since the dawn of civilization, people throughout the world have tried to understand the causes of psychological disorder. The earliest explanations of abnormal behavior focused on possession by gods or demons. Disordered people were seen either as innocent victims of evil spirits or as social or moral deviants suffering supernatural punishment. In Europe during the late Middle Ages, for example, disbelief in established religious doctrine and other unusual behaviors were viewed as the work of the devil or other evil beings. Hundreds of “witches”—mostly women—were burned at the stake, and exorcisms were performed to rid people of their demons. Supernatural explanations of psychological disorders are still invoked today in many cultures around the world—including certain ethnic and religious subcultures in North America (Nickell, 2001; Tagliabue, 1999).

The Biopsychosocial Model

More generally, however, researchers in Western cultures attribute the appearance of psychopathology to three other causes: biological factors, psychological processes, and sociocultural contexts. For many decades, there was controversy over which of these three causes is most important, but it is now widely agreed that they can all be important. Accordingly, researchers have adopted a **biopsychosocial model** in which mental disorders are seen as caused by the combination and interaction of biological, psychological, and sociocultural factors, each of which contributes in varying degrees to particular problems in particular people (U.S. Surgeon General, 1999).

Biological Factors The *biological factors* thought to be involved in causing mental disorders include physical illnesses and disruptions or imbalances in bodily processes. This *medical model* of psychopathology has a long history. For example, the ancient Greek physician Hippocrates said that psychological disorders resulted from imbalances among four *humors*, or bodily fluids (blood, phlegm, black bile, and yellow bile). According to Hippocrates, depression (“melancholia”) resulted from an excess of black bile. In ancient Chinese cultures, psychological disorders were seen as resulting from an imbalance of *yin* and *yang*, the dual forces of the universe flowing in the physical body.

As the medical model gained prominence in Western cultures after the Middle Ages, specialized hospitals for the insane were established throughout Europe. Treatment in these early asylums consisted mainly of physical restraints, laxative purges, bleeding of “excess” blood, and induced vomiting. Cold baths, fasts, and other physical discomforts were also used in efforts to “shock” patients back to normality.

The medical model gave rise to the concept of abnormality as *mental illness*, and to the view in Western cultures today that medical doctors are the proper source of help in the diagnosis and treatment of psychological disorders. The medical model is now more properly called the **neurobiological model**, because it explains psychological disorders in terms of particular disturbances in the anatomy and chemistry of the brain and in other biological processes. Neuroscientists and others who adopt a neurobiological approach study the causes and treatment of these disorders as they would study any physical illness, seeing problematic symptoms stemming primarily from an underlying illness that can be diagnosed, treated, and cured.

The importance of biological factors in psychopathology has been demonstrated in many psychological disorders (Spitzer et al., 1992). *Dementia*, for example, is characterized by a loss of intellectual functions, including disturbances in memory, personality, and cognitive abilities. The most frequent causes of dementia are progressive deterioration of the brain as a result of aging or long-term alcohol

biopsychosocial model A view of mental disorders as caused by a combination of interacting biological, psychological, and sociocultural factors.

neurobiological model A modern name for the medical model, in which psychological disorders are seen as reflecting disturbances in the anatomy and chemistry of the brain and in other biological processes.

An Exorcism Supernatural explanations of mental disorders, as well as supernaturally oriented cures, such as the exorcism being performed by this Buddhist monk in Thailand, remain influential among religious groups in many cultures and subcultures around the world—including some in the United States and other Western countries (Fountain, 2000).

abuse; acute diseases and disorders such as encephalitis, brain tumors, or head injury; and drug intoxication. Alzheimer's disease is a severe form of dementia seen mostly in the elderly. Research in neuroscience and behavioral genetics has also implicated biological factors in a number of other psychological disorders to be described later, including schizophrenia, bipolar disorders, some forms of anxiety disorder, and autism and attention deficit disorder (Kendler, 2001).

Psychological Processes If biological factors provide the “hardware” of mental disorders, the “software” includes psychological factors, such as our wants, needs, and emotions; our learning experiences; and our way of looking at the

Visiting Bedlam As shown here in William Hogarth's portrayal of “Bedlam” (the local name for London's St. Mary of Bethlehem hospital), most eighteenth-century asylums were little more than prisons. Notice the well-dressed visitors; in those days, members of the public could buy tickets to tour the cells and gawk at the patients.

world. The roots of this **psychological model** of mental disorders can be seen in ancient Greek literature and drama dealing with the *psyche*, or mind—especially with the struggles of the mind to resolve inner conflicts or to overcome the effects of stressful events. These ideas gained far greater prominence in the late 1800s, when Sigmund Freud challenged the assumption that psychological disorders had only physical causes. Freud’s explanations of these disorders came as part of his more general *psychodynamic* approach, described in the chapter on personality. Freud viewed psychological disorders as the result of unresolved, mostly unconscious clashes between the desires of the id and the demands of the environment and society. These conflicts, he said, begin early in childhood. Contemporary versions of the psychodynamic model—such as *object relations* theory—focus less on unconscious urges and more on the role of attachment and other early interpersonal relationships (Schultz & Schultz, 2001).

Other theories discussed in the personality chapter suggest other psychological processes that can contribute to the appearance of mental disorders. For example, *social-cognitive* theorists see most psychological disorders as the result of past learning and current situations. Just as people learn to avoid hot grills after being burned, say these theorists, bad experiences in school or a dental office can “teach” people to fear such places. Social-cognitive theorists also emphasize how learned expectations, schemas, and other mental processes discussed in the chapter on cognition and language can influence the development of disorders. Depression, for example, is seen as stemming from negative events, such as losing a job, but also from the irrational or maladaptive thoughts that people have learned in relation to these events—thoughts such as “I never do anything right.”

Finally, the *humanistic* approach to personality suggests that behavior disorders appear when a person’s actualizing tendency is blocked, usually by a failure to be aware of, and to express, true feelings. When this happens, the person’s perceptions of reality become distorted. The greater the distortion, the more serious the psychological disorder.

Sociocultural Context Understanding the neurobiological and psychological factors that contribute to most mental disorders has proven extremely helpful in explaining those disorders. Still, these factors relate mainly to causes residing within the individual. The **sociocultural model** of disorder suggests that we cannot fully explain all forms of psychopathology without also looking outside the individual—at the social and cultural factors that form the context, or background, of abnormal behavior. Looking for causes of disorders in this *sociocultural context* means paying attention to factors such as gender, age, and marital status; the physical, social, and economic situations in which people live; and the cultural values, traditions, and expectations in which they are immersed (Evans et al., 2000; Johnson et al., 1999; Whisman, 1999). Sociocultural context influences not only what is and is not labeled “abnormal” but also who displays what kind of disorder.

Consider gender, for instance. The greater tolerance in many cultures for open expression of emotional distress among women, but not men, may contribute to the higher rates of depression seen in women compared with men (Nolen-Hoeksema, Larson, & Grayson, 1999). And the view held in many cultures that excessive alcohol consumption is less appropriate for women than for men is a sociocultural factor that may help explain higher rates of alcohol abuse among men in those cultures (Helzer et al., 1990).

Sociocultural factors also influence the form that abnormality takes. For example, schizophrenia and depression are *culture-general* disorders—appearing virtually everywhere in the world—but their specific symptoms tend to differ depending on the disordered person’s cultural background (Hopper & Wanderling, 2000). In Western cultures, where emotional and physical components of disorder are generally viewed separately, symptoms of depression tend to revolve around despair and other signs of emotional distress (Kleinman, 1991). But in China and certain other

LINKAGES (a link to Learning)

psychological model A view in which mental disorder is seen as arising from psychological processes.

sociocultural model A way of looking at mental disorders in relation to gender, age, ethnicity, and other social and cultural factors.

Asian cultures where emotional and physical experiences tend to be viewed as one, a depressed person is as likely to report stomach or back pain as to complain of sadness (Brislin, 1993; Parker, Gladstone, & Chee, 2001).

There are also *culture-specific* forms of disorder. For instance, Puerto Rican and Dominican Hispanic women sometimes experience *ataques de nervios*, a unique way of reacting to stress that includes heart palpitations, shaking, shouting, nervousness, depression, and on occasion, fainting or seizure-like episodes (Spiegel, 1994). Another example can be found in Southeast Asia, southern China, and Malaysia, where a disorder called *koro* is occasionally observed. Victims of this condition, who are usually male, fear that their penis will shrivel, retract into the body, and cause death (in females, the fear relates to shriveling of the breasts). *Koro* appears only in cultures holding the specific supernatural beliefs that explain it. In such cultures, epidemics of *koro* are often triggered by economic hard times (Tseng et al., 1992).

In short, as sociocultural factors create differing social roles, stressors, opportunities, and experiences for people who differ in age, gender, and cultural traditions, they help shape the disorders and symptoms to which certain categories of people are prone, and even help shape their response to treatment. For example, among people diagnosed with the severe disorder schizophrenia, those living in a developing country are much more likely to improve than those living in a more developed country (Hopper & Wanderling, 2000). What cultural factor might be responsible for the difference in outcome we do not yet know, but these data highlight the fact that any attempt to fully explain psychological disorders must take sociocultural factors into account.

Diathesis-Stress as an Integrative Explanation

The biopsychosocial model is currently the most comprehensive and influential approach to explaining psychological disorders. It is prominent partly because it encompasses so many important causal factors, including biological imbalances, genetically inherited characteristics, brain damage, enduring psychological traits, socioculturally influenced learning experiences, stressful life events, and many more.

How do all these factors interact to actually create disorder? Most researchers believe that inherited characteristics, biological processes, and early learning experiences combine to create a predisposition, or *diathesis* (pronounced “dye-A-thuh-sis”), for a psychological disorder. Whether or not a person actually develops symptoms of disorder depends on the nature and amount of *stress* the person encounters (National Advisory Mental Health Council, 1996; U.S. Surgeon General, 1999; Zuckerman, 1999). For example, a person may have inherited a biological tendency toward depression or may have learned depressing patterns of thinking, but these predispositions may be expressed as a depressive disorder only after the person is faced with a financial crisis or suffers the loss of a loved one. If such circumstances do not occur, or if the person has adequate skills for coping with stress, depressive symptoms may never appear, or they may be quite mild.

In summary, the **diathesis-stress approach** to explaining psychological disorders assumes that biological, psychological, and sociocultural factors can predispose us toward disorder, but that it takes a certain amount of stress to actually trigger a disorder. For people with a strong diathesis, relatively mild stress might be enough to create a problem. People whose predisposition is weaker might not show signs of disorder until stress becomes extreme or prolonged. Another way to think about the notion of diathesis-stress is in terms of *risk*: The more risk factors for a disorder a person has—whether in the form of genetic tendencies, personality traits, cultural traditions, or stressful life events—the more likely it is that the person will display a form of psychological disorder associated with those risk factors.

Table 15.1 provides an example of how the diathesis-stress approach and the factors contained in the biopsychosocial model of disorder might explain a particu-

diathesis-stress approach Viewing psychological disorders as arising when a predisposition for a disorder combines with sufficient amounts of stress to trigger symptoms

Here are the factors that would be considered by the biopsychosocial model, and combined in the diathesis-stress approach, to explain the case of José, a fifty-five-year-old electronics technician. A previously healthy and vigorous father of two adult children, he was forced to take medical leave because of a series of sudden, uncontrollable panic attacks in which he experienced dizziness, heart palpitations, sweating, and fear of impending death. The attacks also kept him from his favorite pastime, scuba diving, but he has been able to maintain a part-time computer business out of his home. (Panic disorder is discussed in more detail later in this chapter; the outcome of this case is described in the chapter on treatment of psychological disorders.)

table 15.1
Explaining Psychopathology

Explanatory Domain	Possible Contributing Factors
Neurobiological/medical	José may have organic disorders (e.g., genetic tendency toward anxiety; brain tumor, endocrine dysfunction; neurotransmitter imbalance).
Psychological: psychodynamic	José has unconscious conflicts and desires. Instinctual impulses are breaking through ego defenses into consciousness, causing panic.
Psychological: social-cognitive	Physical stress symptoms are interpreted as signs of serious illness or impending death. Panic is rewarded by avoidance of work stress and the opportunity to stay home.
Psychological: humanistic	José fails to recognize his genuine feelings about work and his place in life, and he fears expressing himself.
Sociocultural	A culturally based belief that “a man should not show weakness” amplifies the intensity of stress reactions and delays José’s decision to seek help.
Diathesis-stress summary	José has a biological (possibly genetic) predisposition to be overly responsive to stressors. The stress of work and extra activity exceeds his capacity to cope and triggers panic as a stress response.

lar case of psychopathology. Later in this chapter, you will see how the biopsychosocial model and the diathesis-stress approach are applied to understanding the causes of several other psychological disorders.

Classifying Psychological Disorders

Although definitions of abnormality differ somewhat within and across cultures, there is a set of culture-general and culture-specific behavior patterns that characterize what most mental health professionals consider to be psychopathology. Most of these behavior patterns qualify as disorders because they result in impaired functioning, a main criterion of the practical approach to defining abnormality. It has long been the goal of those who study abnormal behavior to establish a system of classifying such patterns in order to understand and deal with them.

In 1952 the American Psychiatric Association published the first edition of what has become the “official” North American diagnostic classification system, the *Diagnostic and Statistical Manual of Mental Disorders (DSM)*. Each subsequent edition of the *DSM* has included more categories of disorders. The latest editions, *DSM-IV* and *DSM-IV-TR* (which contains some text revisions), include more than three hundred specific diagnostic labels (American Psychiatric Association, 1994, 2000).

Mental health professionals outside North America diagnose mental disorders using the classification systems that appear in the tenth edition of the World Health Organization’s *International Classification of Diseases (ICD-10)* and its companion volume, the second edition of the *International Classification of Impairments, Disabilities and Handicaps (ICIDH-2)*. To facilitate international communication about—and cross-cultural research on—psychopathology, *DSM-IV* was designed to

be compatible with these manuals, and efforts are under way to remove inconsistencies existing between the systems (DeAngelis, 2001).

A Classification System: *DSM-IV*

DSM-IV describes the abnormal patterns of thinking, emotion, and behavior that define various mental disorders. For each disorder, the *DSM* provides specific criteria outlining the conditions that must be met before a person can be diagnosed as having that disorder. Diagnosticians using *DSM-IV* can evaluate troubled people on as many as five dimensions, or *axes*. In keeping with the biopsychosocial model, evaluations on all relevant dimensions are combined to create a broad outline of the person's biological and psychological problems, as well as of any sociocultural factors that might contribute to them. As shown in Table 15.2, major mental disorders, such as schizophrenia or major depressive disorder, are recorded on Axis I, whereas evidence of personality disorders or mental retardation are noted on Axis II. Any medical conditions that might be important in understanding the person's cognitive, emotional, or behavioral problems are listed on Axis III. On Axis IV the diagnostician notes any psychosocial and environmental problems (such as the loss of a loved one, physical or sexual abuse, discrimination, unemployment, poverty, homelessness, inadequate health care, or conflict with religious or cultural traditions) that are important for understanding the person's psychological problems. Finally, a rating (from 100 down to 1) of the person's current level of psychological, social, and occupational functioning appears on Axis V. Here is a sample *DSM-IV* diagnosis for a person who received labels on all five axes:

Axis I Major depressive disorder, single episode; alcohol abuse.

Axis II Dependent personality disorder.

Axis III Alcoholic cirrhosis of the liver.

Axis IV Problems with primary support group (death of spouse).

Axis V Global assessment of functioning = 50.

The terms neurosis and psychosis are no longer major categories in the *DSM* because they are not specific enough; however, some mental health professionals still sometimes use them as shorthand descriptions. *Neurosis* refers to conditions in which some form of anxiety is the major characteristic. *Psychosis* refers to conditions involving more extreme problems that leave people "out of touch with reality" or unable to function on a daily basis. The disorders once gathered under these headings now appear in various Axis I categories in the *DSM-IV*.

Further changes may appear in *DSM-V*, a new edition of the *DSM* that is currently under development. Some experts are proposing, for example, that future diagnoses should consist not only of specific labels, such as "major depression," but also of symptom clusters or symptom dimensions that would be rated in terms of severity (Vollebergh et al., 2001; Widiger & Clark, 2000). This *dimensional approach* would allow each symptom a person displays to be recognized and described, whether or not it is usually associated with a particular diagnostic category. For example, if a person displays symptoms of depression as well as anxiety, both would receive diagnostic attention. By rating the severity of the depressive mood and the intensity of the anxiety, the diagnostician using *DSM-V* would create an even more detailed picture of the problems a person is experiencing.

Purposes and Problems of Diagnosis

A major goal in diagnosing psychological disorders is to determine the nature of people's problems so that the characteristics of those problems can be described and understood, and the most appropriate treatment methods can be chosen. Diagnoses

table 15.2

The *Diagnostic and Statistical Manual of Mental Disorders (DSM)* of the American Psychiatric Association

Axis I (Clinical Syndromes)

1. **Disorders usually first diagnosed in infancy, childhood, or adolescence.** Problems such as hyperactivity, childhood fears, conduct disorders, frequent bed-wetting or soiling, and other problems in normal social and behavioral development. Autistic disorder (severe impairment in social, behavioral, and language development), as well as learning disorders.
2. **Delirium, dementia, and amnesic and other cognitive disorders.** Problems caused by physical deterioration of the brain due to aging, disease, drugs or other chemicals, or other possible unknown causes. These problems can appear as an inability to "think straight" (delirium) or as loss of memory and other intellectual functions (dementia).
3. **Substance-related disorders.** Psychological, behavioral, physical, social, or legal problems caused by dependence on, or abuse of, a variety of chemical substances, including alcohol, heroin, cocaine, amphetamines, hallucinogens, marijuana, and tobacco.
4. **Schizophrenia and other psychotic disorders.** Severe conditions characterized by abnormalities in thinking, perception, emotion, movement, and motivation that greatly interfere with daily functioning. Problems involving false beliefs (delusions).
5. **Mood disorders (also called affective disorders).** Severe disturbances of mood, especially depression, overexcitement (mania), or alternating episodes of each extreme (as in bipolar disorder).
6. **Anxiety disorders.** Specific fears (phobias); panic attacks; generalized feelings of dread; rituals of thought and action (obsessive-compulsive disorder) aimed at controlling anxiety; and problems caused by traumatic events, such as rape or military combat (see the chapter on health, stress, and coping for more on posttraumatic stress disorder).
7. **Somatoform disorders.** Physical symptoms, such as paralysis and blindness, that have no physical cause. Unusual preoccupation with physical health or with nonexistent physical problems (hypochondriasis, somatization disorder, pain disorder).
8. **Factitious disorders.** False mental disorders, which are intentionally produced to satisfy some psychological need.
9. **Dissociative disorders.** Psychologically caused problems of consciousness and self-identification—e.g., loss of memory (amnesia) or the development of more than one identity (multiple personality).
10. **Sexual and gender identity disorders.** Problems of (a) finding sexual arousal through unusual objects or situations (like shoes or exposing oneself), (b) unsatisfactory sexual activity (sexual dysfunction; see the chapter on motivation and emotion), or (c) identifying with the opposite gender.
11. **Eating disorders.** Problems associated with eating too little (anorexia nervosa) or binge eating followed by self-induced vomiting (bulimia nervosa). (See the chapter on motivation and emotion.)
12. **Sleep disorders.** Severe problems involving the sleep-wake cycle, especially an inability to sleep well at night or to stay awake during the day. (See the chapter on consciousness.)
13. **Impulse control disorders.** Compulsive gambling, stealing, or fire setting.
14. **Adjustment disorders.** Failure to adjust to, or deal well with, such stressors as divorce, financial problems, family discord, or other unhappy life events.

Axis II (Personality Disorders and Mental Retardation)

1. **Personality disorders.** Diagnostic labels given to individuals who may or may not receive an Axis I diagnosis but who show lifelong behavior patterns that are unsatisfactory to them or that disturb other people. These patterns may involve unusual suspiciousness, unusual ways of thinking, self-centeredness, shyness, overdependency, excessive concern with neatness and detail, or overemotionality, among others.
2. **Mental retardation.** As described in the chapter on cognitive abilities, the label of mental retardation is applied to individuals whose measured IQ is less than about 70 *and* who fail to display the skills at daily living, communication, and other tasks expected of people their age.

Axis I of the fourth edition (*DSM-IV*) lists the major categories of mental disorders. Personality disorders and mental retardation are listed on Axis II.

are also important for research on the causes of mental disorders. If researchers can accurately and reliably classify people into particular disorder categories, they will have a better chance of spotting genetic features, biological abnormalities, cognitive processes, and environmental experiences that people in the same category might share. And finding that people in one diagnostic category share a set of features that differs from those seen in people in other categories could provide clues to the relative importance of these features in the development of each disorder.

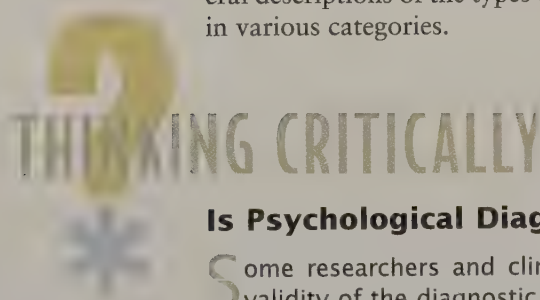

How good is the diagnostic system now in use? One way to evaluate *DSM-IV* is to consider *interrater reliability*, the degree to which different mental health professionals give the same person the same diagnostic label. Some studies indicate that interrater agreement is as high as 83 percent for schizophrenia and mood disorders; agreement on many other Axis I categories is also high (e.g., Foa & Kozak, 1995; Lahey et al., 1994; Nathan & Langenbucher, 1999). Still other categories, such as Axis II personality disorders, remain more difficult to diagnose reliably (Zanarini et al., 2000).

Overall, interrater agreement appears highest when diagnosis is based on structured or semistructured interviews that systematically address various areas of functioning and provide uniform guidelines for interpretation of the answers that people give (Rogers, 1995; Widiger & Sanderson, 1995). In one recent example, diagnosticians using a structured diagnostic interview schedule achieved good to excellent agreement about cases of anxiety and mood disorders (Brown et al., 2001).

Do diagnostic labels give accurate information that guides correct inferences about people? This *validity* question is difficult to answer because it is hard to find a fully acceptable standard for accuracy: Should one diagnosis be evaluated by comparing it with the judgments of experts? Or should it be judged by how well it predicts the diagnosed person's behavior? Still, there is evidence to support the validity of most *DSM* criteria (Clark, Watson, & Reynolds, 1995). And validity is likely to improve further as diagnostic labels—and the diagnostic system—are refined in *DSM-V* to reflect what researchers are learning about the characteristics, causes, courses, and cultural factors involved in various disorders.

The diagnostic system is far from perfect, however (Widiger & Sankis, 2000). First, people's problems often do not fit neatly into a single category. Second, the same symptoms may appear as part of more than one disorder. Third, diagnostic judgments are to some extent subjective, raising the possibility that personal bias might creep into the system. All of these factors can lead to misdiagnosis in some cases. Concern over this possibility is especially relevant as the nations of North America and Western Europe become increasingly multicultural, and as diagnosticians encounter people whose cultural backgrounds they may not fully understand or appreciate. Psychiatrist Thomas Szasz (pronounced “zaws”) and other critics of the medical model (e.g., Caplan, 1995; Kutchins & Kirk, 1997) also argue that labeling people instead of describing problems is dehumanizing, because it ignores features that make each person unique. Calling people “schizophrenics” or “alcoholics,” Szasz says, may actually encourage the behaviors associated with these labels and undermine the confidence of clients (and therapists) about the chances of improvement (Szasz, 1987).

In other words, it is unlikely that any shorthand label can fully describe a person's problems or predict exactly how that person will behave in the future. All that can be reasonably expected of a diagnostic system is that it allows informative, general descriptions of the types of problems displayed by people who have been placed in various categories.

Is Psychological Diagnosis Biased?

Some researchers and clinicians worry that problems with the reliability and validity of the diagnostic system are due partly to bias in its construction and use. They point out, for example, that if the research underlying the diagnostic criteria for a certain disorder focuses mainly on one culture, one gender, one ethnic group, or one age group, those criteria might not apply widely enough. Moreover, because diagnosticians, like other people, hold expectations and make assumptions about males versus females, and about individuals from differing cultures

or ethnic groups, those cognitive biases could color their judgments. This “pre-judging” process could lead them to apply diagnostic criteria in ways that are subtly, but significantly, different from one case to the next (Garb, 1997; Hartung & Widiger, 1998).

What am I being asked to believe or accept?

Here, we focus on ethnicity as a possible source of bias in diagnosing psychopathology. It is of special interest because there is evidence that, like social class and gender, ethnicity is an important sociocultural factor in the development of mental disorder. So the assertion to be considered is that clinicians in the United States base their diagnoses partly on clients’ ethnic background and, more specifically, that there is bias in diagnosing African Americans.

What evidence is available to support the assertion?

Several facts suggest the possibility of ethnic bias in psychological diagnosis. African Americans receive the diagnosis of schizophrenia more frequently than European Americans do (Manderscheid & Barrett, 1987; Pavkov, Lewis, & Lyons, 1989). Further, relative to their presence in the general population, African Americans are overrepresented in public mental hospitals, where the most serious forms of disorder are seen, and underrepresented in private hospitals and outpatient clinics, where less severe problems are treated (Lindsey & Paul, 1989; Snowden & Cheung, 1990; U.S. Surgeon General, 1999).

Are there alternative ways of interpreting the evidence?

Differences among ethnic groups in diagnosis or treatment do not automatically indicate bias based on ethnicity. Perhaps real differences in psychological functioning are associated with different ethnic groups. For example, if, relative to other groups, African Americans are exposed to more risk factors for disorder, such as poverty, violence, or other major stressors, they could be more vulnerable to more serious forms of mental disorder. And poverty, not diagnostic bias, could be responsible for the fact that African Americans more often seek help at less expensive public hospitals than at more expensive private ones.

What additional evidence would help to evaluate the alternatives?

Do African Americans actually display more signs of mental disorder, or do diagnosticians just perceive them as more disordered? One way of approaching this question is to conduct experiments in which diagnosticians assign labels to clients on the basis of case histories, test scores, and the like. In some studies, the cases are selected so that pairs of clients show about the same objective amount of disorder, but one member of the pair is identified as European American and the other as African American. In other studies, the same case materials, identified as representing either African American or European American patients, are presented to different diagnosticians. Bias in diagnosis would be suggested if, for example, patients identified as African American were seen as more seriously disordered than others.

Most studies of this type have found little or no ethnic bias (e.g., Littlewood, 1992). These results are difficult to interpret, however, because the diagnosticians may be aware of the purpose of the study, and so may go out of their way to be unbiased (Abreu, 1999). In fact, researchers have found evidence of some diagnostic bias against African Americans when clinicians were unaware of the purpose of the research (e.g., Baskin, Bluestone, & Nelson, 1981; Jones, 1982).

Bias has also appeared in studies aimed at identifying the factors influencing clinicians’ diagnostic judgments following extensive interviews with patients. One study conducted in a hospital setting found that in arriving at their diagnoses, psychiatrists were more likely to attribute hallucinations and paranoid thinking to African American patients than to patients who were not African American. Symptoms of mood disorders were more likely to be attributed to those who were not African American (Trierweiler et al., 2000). As noted earlier, these differences

anxiety disorder A condition in which intense feelings of apprehension are long-standing and disruptive.

could reflect ethnic differences in the rate of disorder in the population, but when people were interviewed in their own homes as part of large-scale mental health surveys, the diagnosis of schizophrenia was given only slightly more often to African Americans than to European Americans (Robins & Regier, 1991; Snowden & Cheung, 1990). In other words, ethnic bias is suggested, at least for some diagnoses, for patients who are evaluated in mental hospitals (Trierweiler et al., 2000).

• What conclusions are most reasonable?

Just as the diagnostic system is imperfect, so are those who use it. Cognitive biases and stereotypes affect human thinking to some extent in virtually every social situation (see the chapters on cognition and language and on social cognition), so it should not be surprising that they operate in diagnosis as well. But diagnostic bias does not necessarily reflect deliberate discrimination. At least one study has shown that, like the processes of prejudice discussed in the chapter on social cognition, diagnostic bias based on ethnicity can operate unconsciously, without the diagnostician's being aware of it (Abreu, 1999). So no matter how precisely researchers specify the criteria for assigning diagnostic labels, those biases and stereotypes are likely to threaten the objectivity of the diagnostic process (Funtowicz & Widiger, 1999; Trierweiler et al., 2000).

Minimizing diagnostic bias requires a better understanding of it. Toward this end, Hope Landrine (1991) suggests that diagnosticians focus more intently than ever on the fact that their concepts of "normality" and "abnormality" are affected by sociocultural values that they may not share with a given client. And Steven Lopez (1989) argues that diagnosticians must become more aware that the same cognitive shortcuts and biases (see the chapter on cognition and language) that affect everyone else's thinking and decision making can impair their own clinical judgments. In fact, studies of memory, problem solving, decision making, social attributions, and other aspects of culture and cognition may turn out to be key ingredients in reducing bias in the diagnosis of psychological disorders. Meanwhile, perhaps the best way to counteract clinicians' cognitive shortcomings is to teach them to base their diagnoses solely on published diagnostic criteria and statistically validated decision rules (aided, perhaps, by specialized computer programs) rather than relying on their potentially biased clinical impressions (Garb, 1997; Nietzel et al., 2003).

We do not have the space to cover all the *DSM-IV* categories, but we will sample several of the most prevalent and socially significant ones. As you read, try not to catch "medical student's disease." Just as medical students often think they have the symptoms of every illness they read about, some psychology students worry that their behavior (or that of a relative or friend) signals a mental disorder. Remember that everyone has problems sometimes. Before deciding that you or someone you know needs psychological help, consider whether the content, context, and functional impairment associated with the behavior would qualify it as abnormal according to the criteria of the practical approach.

Anxiety Disorders

If you have ever been tense before an exam, a date, or a job interview, you have some idea of what anxiety feels like. Increased heart rate, sweating, rapid breathing, a dry mouth, and a sense of dread are common components of anxiety. Brief episodes of moderate anxiety are a normal part of life for most people. But when anxiety is so intense and long-lasting that it impairs a person's daily functioning, it is called an **anxiety disorder**.

Phobia is the Greek word for “morbid fear,” after the Greek god Phobos. Phobias are usually named using the Greek word for the feared object or situation, followed by the suffix *-phobia*.

table 15.3
Some Phobias

Name	Feared Stimulus	Name	Feared Stimulus
Acrophobia	Heights	Aerophobia	Flying
Claustrophobia	Enclosed places	Entomophobia	Insects
Hematophobia	Blood	Gamophobia	Marriage
Gephyrophobia	Crossing a bridge	Ophidiphobia	Snakes
Kenophobia	Empty rooms	Xenophobia	Strangers
Cynophobia	Dogs	Melissophobia	Bees

Types of Anxiety Disorders

Here we discuss four types of anxiety disorders: *phobia*, *generalized anxiety disorder*, *panic disorder*, and *obsessive-compulsive disorder*. Another type, called *post-traumatic stress disorder*, is described in the chapter on health, stress, and coping. Together, these are the most common psychological disorders in North America.

Phobia An intense, irrational fear of an object or situation that is not likely to be dangerous is called a **phobia**. People who experience phobias usually realize that their fears are groundless, but the resulting discomfort and avoidance of the object or event may greatly interfere with daily life. Thousands of phobias have been described (see Table 15.3).

DSM-IV classifies phobias into specific, social, and agoraphobia subtypes. **Specific phobias** involve fear and avoidance of heights, blood, animals, automobile or air travel, and other specific stimuli and situations. In the United States, they are the most prevalent of the anxiety disorders, affecting 7 to 10 percent of adults and children (Kessler et al., 1994; Robins et al., 1984; U.S. Surgeon General, 1999). Here is an example:

Mr. L. was a fifty-year-old office worker who became terrified whenever he had to drive over a bridge. For years, he avoided bridges by taking round-about ways to and from work, and he refused to be a passenger in anyone else’s car, lest they use a bridge. Even this very inconvenient adjustment failed when Mr. L. was transferred to a position requiring frequent automobile trips, many of which were over bridges. He refused the transfer and lost his job.

Social phobias involve anxiety about being negatively evaluated by others or acting in a way that is embarrassing or humiliating. The anxiety is so intense and persistent that it impairs the person’s normal functioning. Common social phobias are fear of public speaking or performance (“stage fright”), fear of eating in front of others, and fear of using public restrooms (Kleinknecht, 2000). *Generalized social phobia* is a more severe form in which fear occurs in virtually all social situations (Mannuzza et al., 1995). Sociocultural factors can alter the form of social phobias. For example, in Japan, where cultural training emphasizes group-oriented values and goals, a common social phobia is *tai-jin kyofu sho*, fear of embarrassing those around you (Kleinknecht, 1994).

Agoraphobia is a strong fear of being away from a safe place, such as home; of being away from a familiar person, such as a spouse or close friend; or of being in

phobia A strong, irrational fear of an object or situation that does not objectively justify such a reaction.
specific phobias Phobias that involve fear and avoidance of heights, animals, and other specific stimuli and situations.
social phobias Strong, irrational fears relating to social situations.
agoraphobia A strong fear of being away from the security of home.

It's a Long Way Down Almost everyone is afraid of something, but as many as 10 percent of U.S. adults suffer from a specific phobia, in which fear interferes significantly with daily functioning. For example, people with acrophobia (fear of heights) would not do well in a job that requires being in this high position.

a place from which departure might be difficult or where help may be unavailable. Attempts to leave home lead to intense anxiety, so people who suffer severe agoraphobia may become housebound, seldom even trying to go out alone. Theaters, shopping malls, public transportation, and other potentially crowded places are particularly threatening. Most individuals who suffer from agoraphobia have a history of panic attacks, which we describe below. Their intense fear of public places occurs partly because they don't want to risk triggering an attack by going where they had one before or where they feel an attack would be dangerous or embarrassing.

Like other phobias in Western cultures, agoraphobia is more often reported by women. However, in other cultures, such as India, where being a housebound woman is considered less unusual than in the United States, those diagnosed as agoraphobic tend to be male (Raguram & Bhide, 1985). Although agoraphobia occurs less frequently than specific phobias (affecting about 5 percent of the population in the United States), it is the phobia that most often leads people to seek treatment, mainly because it so severely disrupts everyday life (U.S. Surgeon General, 1999).

Generalized Anxiety Disorder Excessive and long-lasting anxiety that is not focused on any particular object or situation marks **generalized anxiety disorder**. Because the problem occurs in virtually all situations and because the person cannot pinpoint its source, this type of anxiety is sometimes called *free-floating anxiety*. For weeks at a time, the person feels anxious and worried, sure that some disaster is about to happen. The person becomes jumpy and irritable; sound sleep is impossible. Fatigue, inability to concentrate, and physiological signs of anxiety are also common. Generalized anxiety disorder affects about 3.4 percent of the U.S. population in any given year, and about 5 percent of the population at some point in their lives (Kessler et al., 1994; U.S. Surgeon General, 1999). It is more common in women, often accompanying other problems such as depression or substance abuse (Wittchen et al., 1994).

generalized anxiety disorder A condition that involves anxiety that is not focused on any particular object or situation.

panic disorder An anxiety disorder involving sudden panic attacks.

Panic Disorder For some people, anxiety takes the form of **panic disorder**. Like the man described in Table 15.1, people suffering from panic disorder experience recurrent, terrifying *panic attacks* that seem to come without warning or obvi-

Anxiety and Depression People who experience anxiety disorders—particularly panic disorder, generalized anxiety disorder, or posttraumatic stress disorder—are likely to display some other mental disorder as well, most often depression (Kaufman & Charney, 2000; Roy-Byrne et al., 2000). Accordingly, the next edition of the *DSM* may include a new category, called *mixed anxiety-depression disorder*, to identify people whose symptoms of anxiety and depression combine to impair their daily functioning (Barlow & Campbell, 2000; Widiger & Clark, 2000).

ous cause. These attacks are marked by intense heart palpitations, pressure or pain in the chest, dizziness or unsteadiness, sweating, and a feeling of faintness. Often, victims believe they are having a heart attack. They may worry constantly about suffering future panic episodes and thus curtail activities to avoid possible embarrassment (Carter & Barlow, 1995). (As noted earlier, fear of experiencing panic attacks while alone or away from home can lead to agoraphobia.) Panic disorder may become a chronic problem, with periods of improvement followed by recurrence (Ehlers, 1995). As many as 30 percent of the people in the United States have experienced at least one panic attack within the past year (Ehlers, 1995), but only about 1.6 percent of the population develops full-blown panic disorder in any given year (Ehlers, 1995; U.S. Surgeon General, 1999). Here is one example:

Geri, a thirty-two-year-old nurse, had her first panic attack while driving on a freeway. Afterward, she would not drive on freeways. Her next attack occurred while with a patient and a doctor in a small examining room. A sense of impending doom flooded over her, and she burst out of the office and into the parking lot, where she felt immediate relief. From then on, fear of another attack made it impossible for her to tolerate any close quarters, including crowded shopping malls. She eventually quit her job because of terror of the examining rooms.

Obsessive-Compulsive Disorder Anxiety is also at the root of obsessive-compulsive disorder (OCD), which affects about 2.4 percent of the U.S. population in any given year (U.S. Surgeon General, 1999). Like Mark, whose story opened this chapter, people displaying obsessive-compulsive disorder are plagued by persistent, upsetting, and unwanted thoughts—called *obsessions*—that often center on the possibility of infection, contamination, or doing harm to oneself or others. They do not actually carry out harmful acts, but the obsessive thoughts motivate ritualistic, repetitive behaviors—called *compulsions*—that the person performs in an effort to avoid some dreaded outcome or to reduce feelings of anxiety associated with the obsessions (Foa & Kozak, 1995). For example, Mark engaged in incessant, ritualized cleaning to protect himself from infection; other common compulsions include rituals such as checking locks; repeating words, images, or numbers; counting things; or arranging objects “just so.” Obsessions and compulsions are much more intense than the familiar experience of having a repetitive thought or tune “in the back of your mind” or rechecking that a door is locked. In obsessive-compulsive

obsessive-compulsive disorder (OCD)
An anxiety disorder involving repetitive thoughts and urges to perform certain rituals.

A Cleaning Compulsion Obsessive-compulsive disorder is diagnosed when a culturally expected degree of cleanliness evolves into an obsessive preoccupation with germs and a life-disrupting compulsion to clean things. Although learning and stress appear to play the major role in shaping and triggering this and other anxiety disorders, biological factors, including genetically inherited characteristics and deficiencies in certain neurotransmitters (see the chapter on biological aspects of psychology), may result in an oversensitive nervous system and a predisposition toward anxiety.

disorder, the obsessions and compulsions are intense, disturbing, and often bizarre intrusions that can severely impair daily activities. (*DSM-IV* defines compulsions as taking up more than one hour a day.) Many people who display this disorder recognize that their thoughts and actions are irrational, but they still experience severe agitation and anxiety if they try to interrupt their obsessions or give up their compulsive behaviors.

Causes of Anxiety Disorders

As with all the forms of psychopathology we will consider, the exact causes of anxiety disorders are a matter of debate. However, there is good evidence that biological, psychological, and social factors all contribute. Biological predispositions, distortions in thinking, and certain learning experiences appear to be particularly important (U.S. Surgeon General, 1999).

Biological Factors

Genetic influences on anxiety disorders are suggested by research showing that if one identical twin has an anxiety disorder, the other is more likely also to have an anxiety disorder than is the case in nonidentical twin pairs (Hettema, Neale, & Kendler, 2001; Kendler et al., 1992). In fact, most anxiety disorders, including panic disorder, obsessive-compulsive disorder, and generalized social phobia, appear to run in families (Kendler et al., 1995, 2001; Pauls et al., 1995; Skre et al., 2000; Wittchen et al., 1994). Some people who display these disorders may have inherited an autonomic nervous system that is oversensitive to stress, thus predisposing them to react with anxiety to a wide range of situations (Zinbarg & Barlow, 1996). There may be more specific predispositions as well. One study has found that identical twins were more likely than other siblings to share phobias of small animals and social situations, but not of heights or enclosed spaces (Skre et al., 2000).

A predisposition for developing anxiety disorders may also stem from abnormalities in the brain's neurotransmitter systems, which are discussed in the chapter on biological aspects of psychology. Excessive activity of norepinephrine in certain parts of the brain has been linked with panic disorder, and dysregulation of serotonin has been associated with obsessive-compulsive disorder. In addition, there is evidence that anxiety-generating neural impulses may run unchecked when the neurotransmitter GABA is prevented from exerting its normal inhibitory influence in certain neural pathways (Friedman, Clark, & Gershon, 1992; Zorumski & Isenberg, 1991).

Something may also be physically wrong in people with panic disorder. Unlike other people, many of these individuals have a panic episode after receiving an injection of lactate or caffeine, inhaling carbon dioxide, or taking yohimbine (a drug that blocks one type of norepinephrine receptor) (Papp et al., 1993). Because these substances all stimulate brainstem areas that control the autonomic nervous system, one hypothesis is that panic-disorder patients have hypersensitive brainstem mechanisms and are therefore especially prone to fear responses (Gorman et al., 1989).

Cognitive Factors

Although biological predispositions may set the stage for anxiety disorders, most researchers agree that environmental stressors and psychological factors, including cognitive processes and learning, are crucial to the development of most anxiety disorders (Ley, 1994; Schmidt, Lerew, & Jackson, 1997; Schmidt et al., 2000). Persons suffering from an anxiety disorder may exaggerate the dangers in their environment, thereby creating an unrealistic expectation that bad events are going to happen (Foa et al., 1996). In addition, they tend to underestimate their own capacity for dealing with threatening events, resulting in anxiety and desperation when feared events do occur (Beck & Emery, 1985).

As an example, consider the development of a panic attack. Whereas the appearance of unexplained symptoms of physical arousal may make a panic attack

more likely, the person's cognitive interpretation of those symptoms can determine whether or not the attack actually develops (Clark et al., 1997; Schmidt, Lerew, & Jackson, 1999). One study, for instance, found that panic attacks were much less likely if panic-disorder patients believed they could control the source of their discomfort (Rapee et al., 1992). In another study, panic-disorder patients were asked to inhale carbon dioxide, which typically causes panic attacks in such patients. Those who inhaled this substance in the presence of a person they associated with safety were significantly less fearful than patients whose "safe person" was not present (Carter et al., 1995). Results like these suggest a role for cognitive factors in panic disorder.

LINKAGES (a link to Learning)

Anxiety Disorders and Learning

The learning principles discussed in the chapter on learning also play an important role in anxiety disorders. For example, upsetting thoughts—about money or illness, for example—often create anxiety and worry, especially when people are already under stress or feel incapable of dealing with their problems. As the thoughts become more persistent, anxiety increases. If, say, cleaning the kitchen temporarily relieves the anxiety, that action may be strengthened through the process of negative reinforcement discussed in the chapter on learning. But such actions do nothing to eliminate the obsessive thoughts, so they return, and the actions become compulsive, endlessly repeated rituals that keep the person trapped in a vicious circle of anxiety (Barlow, 1988). So to social-cognitive theorists, obsessive-compulsive disorder is a pattern that is sparked by distressing thoughts and maintained by operant conditioning.

Phobias may also be based in part on the principles of classical conditioning and observational learning described in the chapter on learning. The object of the

Learning by Watching Many phobias, including those of needles, blood, and medical-related situations, are acquired vicariously. Fear developed through observational learning can be as strong as fear developed through direct experience (Kleinknecht, 1991), though direct conditioning is the more common pathway to a phobia (Öst, 1992). Fearlessness can also be learned vicariously. By simply watching the boy in the dental chair as he learns to relax with his dentist, the other youngster is less likely to be distressed when it is his turn.

Biological Preparedness

Having a predisposition to learn fear of snakes and other potentially dangerous stimuli makes evolutionary sense. Animals (and humans) who rapidly learn a fear response to objects or situations that they see frightening their parents or peers are more likely to survive to pass on their genes to the next generation. Make a list of the things that you might be especially afraid of. How did these fears develop? And how many of them appear to have “survival value”?

phobia becomes an aversive conditioned stimulus through association with a traumatic event that acts as an unconditioned stimulus (Öst, 1992). Fear of dogs, for example, may result from a dog attack. But just seeing or hearing about other people's bad experiences might produce the same result (most people who fear flying have never been in a plane crash). Once phobias are learned, avoiding the feared object or situation prevents the person from finding out that there is no need to be afraid. This cycle of avoidance helps explain why many phobias do not simply extinguish, or disappear, on their own.

Why are phobias about snakes and spiders so common, even though people are seldom harmed by them? And why are there so few cases of electrical-shock phobia, even though lots of people receive accidental electrical shocks? As discussed in the chapter on learning, the answer may be that people are *biologically prepared* to learn associations between certain stimuli and certain responses. These stimuli and responses, then, would be especially easy to link through conditioning (Hamm, Vaitl, & Lang, 1989). Specifically, people may be biologically prepared to learn to fear and to avoid stimuli that had the potential to harm their evolutionary ancestors (Skre et al., 2000; Staddon & Ettinger, 1989).

Some laboratory evidence supports the notion that people are biologically prepared to learn certain phobias. A group of Swedish psychologists attempted to classically condition people to fear certain stimuli by associating the stimuli with electrical shocks (Öhman, Dimberg, & Öst, 1985). The participants developed approximately equal conditioned anxiety reactions to photos of houses, human faces, and snakes. Later, however, when they were tested without shock, the reaction to snakes remained long after the houses and faces had lost their ability to elicit a fear response. A series of investigations with animals has also supported preparedness theory (Cook & Mineka, 1990). If a monkey sees another monkey behaving fearfully in the presence of a snake, it quickly develops a strong and persistent fear of snakes. However, if the snake is entwined in flowers, the observer monkeys come to fear only the snake, not the flowers. So fear conditioning was selective, focusing only on potentially dangerous creatures such as snakes or crocodiles (Zinbarg & Mineka, 1991), not on harmless objects. Data like these suggest that anxiety disorders probably arise through the combined effects of genetic predispositions and learning.

Somatoform Disorders

When an athlete's fainting spells prevented her from competing in track and field events, doctors examined her but could find nothing physically wrong. After a program of stress management, however, her symptoms disappeared, and she was able to rejoin her team (Lively, 2001). Sometimes people show symptoms of a *somatic*, or bodily, disorder, even though there is no physical cause. Because these conditions reflect psychological problems that take somatic form, they are called **somatoform disorders**. The classic example is **conversion disorder**, a condition in which a person appears to be, but is not, blind, deaf, paralyzed, or insensitive to pain in various parts of the body. (An earlier term for this disorder was *hysteria*.) Conversion disorders are rare, accounting for only about 2 percent of diagnoses (American Psychiatric Association, 1994, 2000). Although they can occur at any point in life, they usually appear in adolescence or early adulthood.

Conversion disorders differ from true physical disabilities in several ways. First, they tend to appear when a person is under severe stress. Second, they often help reduce that stress by enabling the person to avoid unpleasant or threatening situations. Third, the person may show remarkably little concern about what is apparently a rather serious problem. Finally, the symptoms may be physiologically impossible or improbable, as Figure 15.2 illustrates. One university student, for example, experienced visual impairment that began each Sunday evening and became total blindness by Monday morning. Her vision would begin to return on Friday evenings and was fully restored in time for weekend football games and other social activities. She expressed no undue concern over her condition (Holmes, 1991).

Can people who display a conversion disorder see and hear, even though they act as if they cannot? Experiments show that they can (Grosz & Zimmerman, 1970), but this does not necessarily mean that they are malingering, or lying. Research on consciousness suggests that people can use sensory input even when they are not consciously aware of doing so (e.g., Blake, 1998). Rather than destroying visual or auditory ability, the conversion process may prevent the person from being aware of information that the brain is still processing (Halligan & David, 1999).

Another somatoform disorder is **hypochondriasis** (pronounced "hye-poh-kon-DRY-a-sis"), a strong, unjustified fear that one has cancer, heart disease, AIDS, or other serious physical problems. The fear prompts frequent visits to physicians and reports of numerous symptoms. Their preoccupation with illness often leads hypochondriacs to become experts on their most feared diseases. In some ways, hypochondriasis resembles a phobic anxiety disorder, but whereas a phobic person might suffer irrational fear of getting a serious illness, the hypochondriac is excessively concerned about already *having* the illness. A related condition, called **somatization disorder**, is characterized by dramatic, but often vague, reports about a multitude of physical problems rather than any specific illness. Finally, **pain disorder** is marked by complaints of severe, often constant pain (typically in the neck, chest, or back) with no physical cause.

Some cases of somatoform disorder may be related to childhood experiences in which a person learns that symptoms of physical illness bring special attention, care, and nurturance (Barsky et al., 1994). Others, including conversion disorder, may be triggered by severe stressors (Spiegel, 1994). Based on such findings, many researchers have adopted a diathesis-stress approach rather than seeking a common cause for all somatoform disorders (e.g., Nietzel et al., 1998). The results of their work suggest that certain people may have biological and psychological traits that make them especially vulnerable to somatoform disorders, particularly when combined with a history of physical illness. Among these traits are self-consciousness and oversensitivity to physical sensations. If such people experience a number of long-lasting stressors, intense emotional conflicts, or severe traumas, they are more likely than others to display physical symptoms in association with emotional arousal (Nietzel et al., 1998).

somatoform disorders Psychological problems in which there are symptoms of a physical disorder without a physical cause.

conversion disorder A somatoform disorder in which a person displays blindness, deafness, or other symptoms of sensory or motor failure without a physical cause.

hypochondriasis A strong, unjustified fear of physical illness.

somatization disorder A somatoform disorder in which there are numerous physical complaints without verifiable physical illness.

pain disorder A somatoform disorder marked by complaints of severe pain with no physical cause.

figure 15.2**Glove Anesthesia**

In glove anesthesia, a form of conversion disorder, lack of feeling stops abruptly at the wrist (Part B). But as shown in Part A, the nerves of the hand and arm blend, so if they were actually impaired, part of the arm would also lose sensitivity. Other neurologically impossible symptoms of conversion disorder include sleepwalking at night on legs that are “paralyzed” during the day.

Sociocultural factors may also shape some somatoform disorders. For example, in many Asian, Latin American, and African cultures, it is not unusual for people to experience severe physical symptoms in association with psychological or interpersonal conflicts, whereas in North America such conflicts are more likely to result in anxiety or depression (Brislin, 1993). Genetic factors do not seem to be important in somatoform disorders.

Dissociative Disorders

If you have ever spent many hours driving on a boring highway, you may have suddenly realized that you had little or no recollection of what happened during the last half-hour. This common experience does not signal a mental disorder, but when disruptions in a person's memory, consciousness, or identity are more intense and long-lasting, they are known as **dissociative disorders**. These disruptions can come on gradually, but they usually occur suddenly and last from a few hours to many years.

Consider the case of John, a thirty-year-old computer manufacturing executive. John was a meek person who was dependent on his wife for companionship and emotional support. It came as a jolt when she announced that she was leaving him to live with his younger brother. John did not go to work the next day. In fact, nothing was heard from him for two weeks. Then he was arrested for public drunkenness and assault in a city more than three hundred miles from his home. The police discovered that during those two weeks, John lived under another name at a cheap hotel and worked selling tickets at a pornographic movie theater. When he was interviewed, John did not know his real name or his home address, could not explain how he had reached his present location, and could not remember much about the previous two weeks.

John's case illustrates the dissociative disorder known as **dissociative fugue**, which is characterized by a sudden loss of personal memory and the adoption of a new identity in a new locale. Another dissociative disorder, **dissociative amnesia**, also involves sudden memory loss. As in fugue, all personal identifying information may be forgotten, but the person does not leave home or create a new identity. These rare conditions attract intense publicity because they are so dramatic.

The most famous dissociative disorder is **dissociative identity disorder (DID)**, formerly known as—and still commonly called—*multiple personality disorder*

dissociative disorders Rare conditions that involve disruptions in a person's memory, consciousness, or identity.

dissociative fugue A sudden loss of memory and the assumption of a new identity in a new locale.

dissociative amnesia A disorder marked by a sudden loss of memory.

dissociative identity disorder (DID) A dissociative disorder in which a person reports having more than one identity.

A Famous Case of Dissociative Identity Disorder In this scene from the film *Sybil*, Sally Field portrays a woman diagnosed with dissociative identity disorder, previously known as multiple personality disorder, whose behavior created the appearance of as many as seventeen distinct personalities. The causes of such dramatic cases, and the reasons behind their increasing incidence in recent years, are a matter of intense debate.

(MPD). Dissociative identity disorder is a condition in which a person appears to have more than one identity, each of which speaks, acts, and writes in a different way. Each personality seems to have its own memories, wishes, and (often conflicting) impulses. Here is a case example:

Mary, a pleasant and introverted thirty-five-year-old social worker, was referred to a psychiatrist for hypnotic treatment of chronic pain. At an early interview she mentioned the odd fact that though she had no memory of using her car after coming home from work, she often found that it had been driven fifty to one hundred miles overnight. It turned out that she also had no memory of large parts of her childhood. Mary rapidly learned self-hypnosis for pain control, but during one hypnotic session, she suddenly began speaking in a hostile manner. She told the doctor her name was Marian, and that it was “she” who had been taking long evening drives. She also called Mary “pathetic” for “wasting time” trying to please other people. Eventually, six other identities emerged, some of whom told of having experienced parental abuse in childhood. (Spitzer et al., 1994)

How do dissociative disorders develop? Psychodynamic theorists see massive repression of unwanted impulses or memories as the basis for creating a “new person” who acts out otherwise unacceptable impulses or recalls otherwise unbearable memories (Ross, 1997). Social-cognitive theorists focus on the fact that everyone is capable of behaving in different ways, depending on circumstances (e.g., boisterous in a bar, quiet in a museum); but in rare cases, they say, this variation can become so extreme that an individual feels—and is perceived by others as being—a “different person.” Further, dissociative symptoms may be strengthened by reward as people find that a sudden memory loss or shift in behavior allows them to escape stressful situations, responsibilities, or punishment for misbehavior (Lilienfeld et al., 1999).

Evaluating these hypotheses has been difficult, in part because of the rarity of dissociative disorders. Recently, however, dissociative identity disorder has been diagnosed more frequently, either because clinicians are looking for it more carefully or because the conditions leading to it are more prevalent. Research available so far supports three conclusions. First, many people displaying DID have experienced events they would like to forget or avoid. The majority (some clinicians believe all) have suffered severe, unavoidable, persistent abuse in childhood (Ross et al., 1991). Second, like Mary, most of these people appear to be skilled at self-hypnosis, through which they can induce a trance-like state. Third, most found that they could escape the trauma of abuse at least temporarily by creating “new personalities” to deal with stress (Spiegel, 1994). However, not all abused children display dissociative identity disorder, and there is evidence that some cases of dissociative identity disorder may have been triggered by media stories or by suggestions made to clients by their therapists (Spanos, 1996).

This evidence has led some skeptics to question the existence of multiple personalities (Acocella, 1998); others suggest that the increased incidence of dissociative identity disorder may simply reflect its status as a socioculturally approved method of expressing distress (Hacking, 1995; Spanos, 1994). In fact, it was observations such as these that prompted the change in its official designation from *multiple personality disorder* to *dissociative identity disorder*. The authors of *DSM-IV* made this change partly to avoid perpetuating the notion that people harbor multiple personalities that can easily be “contacted” through hypnosis or related techniques. The new name was chosen to suggest, instead, that dissociation, or separation, between one’s memories and other aspects of identity can be so dramatic that people experiencing it may come to believe that they have more than one personality (Gleaves, May, & Cardena, 2001; Spiegel, 1994). Research on the existence and alleged effects of repressed memories—discussed in the chapter on memory—is sure to have an impact on our understanding of, and the controversy over, the causes of dissociative identity disorder. (“In Review: Anxiety, Somatoform, and Dissociative Disorders” presents a summary of our discussion of these disorders.)

Debate and skepticism about the nature and origins of dissociative identity disorder is not confined to professional journals. This cartoon appeared recently in the *New Yorker*.

Anxiety, Somatoform, and Dissociative Disorders

Disorder	Subtypes	Major Symptoms
Anxiety disorders	Phobias	Intense, irrational fear of objectively nondangerous situations or things, leading to disruptions of behavior
	Generalized anxiety disorder	Excessive anxiety not focused on a specific situation or object; free-floating anxiety
	Panic disorder	Repeated attacks of intense fear involving physical symptoms such as faintness, dizziness, and nausea
	Obsessive-compulsive disorder	Persistent ideas or worries accompanied by ritualistic behaviors performed to neutralize the anxiety-driven thoughts
Somatoform disorders	Conversion disorder	A loss of physical ability (e.g., sight, hearing) that is related to psychological factors
	Hypochondriasis	Preoccupation with, or belief that, one has serious illness in the absence of any physical evidence
	Somatization disorder	Wide variety of somatic complaints that occur over several years and are not the result of a known physical disorder
	Pain disorder	Preoccupation with pain in the absence of physical reasons for the pain
Dissociative disorders	Dissociative fugue	Sudden, unexpected loss of memory, which may result in relocation and the assumption of a new identity
	Dissociative identity disorder (multiple personality disorder)	Appearance within the same person of two or more distinct identities, each with a unique way of thinking and behaving

Mood Disorders

Everyone's mood, or *affect*, tends to rise and fall from time to time. However, when people experience extremes of mood—wild elation or deep depression—for long periods, when they shift from one extreme to another, and especially when their moods are not consistent with the events around them, they are said to show a **mood disorder** (also known as *affective disorder*). We will describe two main types: depressive disorders and bipolar disorders.

Depressive Disorders

Depression can range from occasional, normal “down” periods to episodes severe enough to require hospitalization. A person suffering **major depressive disorder** feels sad and overwhelmed for weeks or months, typically losing interest in activities and relationships and taking pleasure in nothing (Coryell et al., 1993; Sloan, Strauss, & Wisner, 2001). Exaggerated feelings of inadequacy, worthlessness, hopelessness, or guilt are common. Despite the person's best efforts, everything from conversation to bathing is an unbearable, exhausting effort (Solomon, 1998). Changes in eating habits resulting in weight loss or weight gain often accompany major depressive disorder, as does sleep disturbance or, less often, excessive sleeping. Problems in working, concentrating, making decisions, and thinking clearly are also common. More often than not, there are also symptoms of an accompanying anxiety disorder (Zimmerman, McDermt, & Mattia, 2000). In extreme cases, depressed people may express false beliefs, or **delusions**—worrying, for example, that the government is planning to punish them. Major depressive disorder may come on suddenly or gradually. It may consist of a single episode or, more commonly, repeated depressive periods. Here is a case example:

Mr. J. was a fifty-one-year-old industrial engineer. . . . Since the death of his wife five years earlier, he had been suffering from continuing episodes of depression marked by extreme social withdrawal and occasional thoughts of suicide. . . . He drank and, when thoroughly intoxicated, would plead to his deceased wife for forgiveness. He lost all capacity for joy: . . . Once a gourmet, he now had no interest in food and good wine . . . and could barely manage to engage in small talk. As might be expected, his work record deteriorated markedly. Appointments were missed and projects haphazardly started and left unfinished. (Davison & Neale, 1990, p. 221)

Depression is not always so extreme. In a less severe pattern of depression, called **dysthymic disorder**, the person experiences the sad mood, lack of interest, and loss of pleasure associated with major depression, but less intensely and for a longer period. (The duration must be at least two years to qualify as dysthymic disorder.) Mental and behavioral disruption are also less severe; people exhibiting dysthymic disorder rarely require hospitalization.

Major depressive disorder occurs sometime in the lives of up to 17 percent of the North American or European population; at any given time, about 6.5 percent of these people are affected (Blazer et al., 1994; Kessler et al., 1994; U.S. Surgeon General, 1999). Anyone can become depressed, but major depressive disorder is most likely to appear during the late teenage and early adult years (Burke et al., 1990); there is also evidence that rates of depression have increased among young people (Cross-National Collaborative Group, 1992; Fassler & Dumas, 1997). In the United States and other Western countries, women are two to three times more likely than men to experience major depressive disorder (Weissman et al., 1993). However, there are no reported gender differences in depression in some less economically developed countries in the Middle East, Africa, and Asia (Culbertson, 1997).

mood disorder A condition in which a person experiences extreme moods, such as depression or mania.

major depressive disorder A condition in which a person feels sad and hopeless for weeks or months.

delusions False beliefs, such as those experienced by people suffering from extreme depression.

dysthymic disorder A pattern of comparatively mild depression that lasts for at least two years.

Suicide and Depression Suicide is associated with a variety of psychological disorders, but it is most closely tied to depression; some form of depression has been implicated in 40 to 60 percent of suicides (Angst, Angst, & Stassen, 1999; Clark & Fawcett, 1992). In fact, thinking about suicide is a symptom of depressive disorders. Hopelessness about the future—another depressive symptom—and a desire to seek instant escape from problems are also related to suicide attempts (Beck et al., 1990; Brown et al., 2000).

About 31,000 people in the United States and Canada commit suicide each year, and 10 to 20 times that many people attempt it (Statistics Canada, 1998; U.S. Surgeon General, 1999). Worldwide, the annual death toll from suicide is 120,000. Suicide rates differ considerably depending on sociocultural factors such as age, gender, and ethnicity. The rate is as high as 25 per 100,000 individuals in some northern European countries and Japan (Lamar, 2000), and as low as 6 per 100,000 in countries with stronger religious prohibitions against suicide, such as Greece, Italy, Ireland, and the nations of the Middle East.

In the United States, where the overall suicide rate is about 10.6 per 100,000, suicide is most common among people 65 years old and older; the rate for those over 85 years old is 21 per 100,000 (Centers for Disease Control and Prevention, 1999d; Hoyert, Kochanek, & Murphy, 1999; U.S. Surgeon General, 1999). However, since 1950, suicide among adolescents—especially 15- to 19-year-olds—has tripled. It is now the third leading cause of death among adolescents (Centers for Disease Control and Prevention, 1999d). Suicide is the second leading cause of death among college students; about 10,000 try to kill themselves each year, and about 1,000 succeed. These figures are much higher than for 18- to 24-year-olds in general, but much lower than for the elderly (U.S. Surgeon General, 1999). Women attempt suicide 3 times as often as men, but men are 4 times as likely to actually kill themselves (Centers for Disease Control and Prevention, 1999). And among depressed people, men—at a rate of 65 per 100,000—are 10 times more likely than women to commit suicide (Blair-West et al., 1999; Centers for Disease Control and Prevention, 1999d).

Suicide rates also differ across ethnic groups in the United States (Oquendo et al., 2001; see Figure 15.3). For example, although there is wide variation from tribe to tribe, the overall rate for American Indians is 13.6 per 100,000, compared with 12.9 for European Americans, 9.1 for Asian Americans, 7.5 for Hispanic Americans, and 5.7 for African Americans (Centers for Disease Control and Prevention, 1999d; Garland & Zigler, 1993; Howard-Pitney et al., 1992; McIntosh,

figure 15.3

Suicide Rates in Various Ethnic Groups

The suicide rates among ethnic groups in the United States vary widely. For example, the rate among American Indians is more than twice that of African Americans. In 1997, more teenagers and young adults died from suicide than from cancer, heart disease, AIDS, birth defects, stroke, pneumonia and influenza, and chronic lung disease *combined* (Centers for Disease Control and Prevention, 1999d).

1992). The suicide rate among male European American teenagers, an alarming 16 per 100,000, has actually dropped from a high of 18 per 100,000 in 1986. However, the rate has increased from 7.1 to 11.4 per 100,000 for African American teens, and it stands at 62 per 100,000 among American Indian adolescents—the highest rate in the United States (Centers for Disease Control and Prevention, 1999d).

Predicting who will commit suicide is difficult. For one thing, suicidal thoughts are quite common—5.6 percent of all adults and as many as 10 percent of college students report having had such thoughts in the previous year (Brenner, Hassan, & Barrios, 1999; Crosby, Cheltenham, & Sacks, 1999). Still, the results of hundreds of research studies provide some predictive guidelines. In the United States, at least, suicide is most likely among European American males, especially those over forty-five, single or divorced, and living alone. The risk of suicide is also heightened among people who have made a specific plan, have given away possessions (Clark et al., 1989), and are impulsive (Corruble, Damy, & Guelfi, 1999). Among the elderly, suicide is most common among men who are depressed about health problems (U.S. Surgeon General, 1999). A previous suicide attempt may not always be a good predictor of eventual suicide, because such attempts may have been help-seeking gestures, not failed efforts to die. In fact, although about 10 percent of unsuccessful attempters try again and succeed, most people who commit suicide had made no prior attempts (Clark & Fawcett, 1992).

One myth about suicide is that people who talk about it will never try it. On the contrary, those who say they are thinking of suicide are much more likely to attempt suicide than people from the general population. In fact, according to Edwin Schneidman (1987), 80 percent of suicides are preceded by some kind of warning, whether direct (“I think I’m going to kill myself”) or vague (“Sometimes I wonder if life is worth living”). Although not everyone who threatens suicide follows through, if you suspect that someone you know is thinking about suicide, encourage the person to contact a mental health professional or a crisis hotline. If the danger is imminent, make the contact yourself, and ask for advice about how to respond. Many suicide attempts—including those triggered by other suicides in the same town or school—can be prevented by social support and other forms of help for people at high risk (Joiner, 1999). For more information, visit suicide-related web sites, such as that of the American Association of Suicidology (www.suicidology.org).

Bipolar Disorders

The alternating appearance of two emotional extremes, or poles, characterizes *bipolar I disorder*. We have already described one emotional pole: depression. The other is **mania**, which is a very agitated, usually elated, emotional state. People in a manic state tend to be utterly optimistic, boundlessly energetic, certain of having extraordinary powers and abilities, and bursting with all sorts of ideas. They become irritated with anyone who tries to reason with them or “slow them down.” During manic episodes individuals may make impulsive and unwise decisions, including spending their life savings on foolish schemes.

In **bipolar I disorder**, manic episodes may alternate with periods of deep depression (sometimes, periods of relatively normal mood separate these extremes). This pattern has also been called *manic depression*. Compared with major depressive disorder, bipolar I disorder is rare; it occurs in only about 1 percent of adults, and it affects men and women about equally. However, it can severely disrupt a person’s ability to work or maintain social relationships (Goldberg, Harrow, & Grossman, 1995). Even less common is *bipolar II disorder*, which features major depressive episodes alternating with episodes known as *hypomania*, which are less severe than the manic phases seen in bipolar I disorder.

A somewhat more common mood disorder is **cyclothymic disorder**, the bipolar equivalent of dysthymia. Cyclothymic disorder involves episodes of depression and

mania A very active, usually elated, emotional state.

bipolar I disorder A condition in which a person alternates between deep depression and mania.

cyclothymic disorder A form of bipolar disorder characterized by comparatively mild mood swings.

in review Mood Disorders

Type	Typical Symptoms	Related Features
Major depressive disorder	Deep sadness, feelings of worthlessness, changes in eating and sleeping habits, loss of interest and pleasure	Lasts weeks or months; may occur in repeating episodes; severe cases may include delusions; danger of suicide
Dysthymic disorder	Similar to major depressive disorder, but less severe and longer lasting	Hospitalization usually not necessary
Bipolar I disorder	Alternating extremes of mood, from deep depression to mania, and back	Manic episodes include impulsivity, unrealistic optimism, high energy, severe agitation
Cyclothymic disorder	Similar to bipolar disorder, but less severe	Hospitalization usually not necessary

mania, but the intensity of both moods is less severe than in cases of bipolar I disorder. (“In Review: Mood Disorders” summarizes the main types of mood disorders.)

Causes of Mood Disorders

Research on the causes of mood disorders has focused on biological, psychological, and sociocultural risk factors. The more of these risk factors people have, the more likely they are to experience a mood disorder.

Biological Factors The role of genetics in mood disorders, especially in bipolar disorders, is suggested by twin studies and family studies (Kelsoe et al., 2001). For example, bipolar disorder is much more likely to be seen in both members of genetically identical twin pairs than in fraternal, or genetically nonidentical, twins (Bowman & Nurnberger, 1993; Egeland et al., 1987; NIMH, 1998a). Family studies also show that those who are closely related to people with a bipolar disorder are more likely than others to develop that disorder themselves (Winokur et al., 1995). Major depressive disorder is also more likely to be shared among family members, and especially by identical twins (Kendler et al., 1995; Klein et al., 2001; Nurnberger, 1993). This genetic influence is especially strong in female twins (Bierut et al., 1999). Researchers continue to look for the specific genes that might be involved in the transmission of elevated risk for mood disorders (Baron, 1997; U.S. Surgeon General, 1999).

Other potential biological causes of mood disorders include imbalances in the brain’s neurotransmitter systems, malfunctioning of the endocrine system, disruption of biological rhythms, and according to a recent theory, reduced development in the brain’s frontal lobes (Cotter et al., 2001), all of which may themselves be influenced by genetics. Neurotransmitters such as norepinephrine, serotonin, and dopamine were implicated decades ago, when scientists discovered that drugs capable of altering these brain chemicals also relieved mood disorders. Early research suggested that depression was triggered by too little of these neurotransmitters, whereas unusually high levels caused mania; but the neurochemical causes now appear more complex than that. Recent research suggests, for example, that mood disorders may result in part from changes in the sensitivity of the neuronal receptors at which these chemicals have their effects in the brain. The precise nature of these neurotransmitter-

LINKAGES (a link to Biological Aspects of Psychology)

Treating SAD Seasonal affective disorder (SAD) can often be relieved by exposure to full-spectrum light for as little as a couple of hours a day (Campbell & Murphy, 1998; Sato, 1997).

receptor mechanisms, and just how they affect mood, is not yet fully understood (Martinot et al., 2001; Schloss & Williams, 1998; U.S. Surgeon General, 1999).

Mood disorders have also been related to malfunctions of the endocrine system, especially the hypothalamic-pituitary-adrenocortical system (HPA), mentioned in the chapter on health, stress, and coping as being involved in the body's responses to stress. For example, research shows that as many as 70 percent of depressed people secrete abnormally high levels of the stress hormone *cortisol* (Dinan, 2001; Nemeroff, 1998; Posener et al., 2000).

The cyclical pattern seen in bipolar disorders and in recurring episodes of major depressive disorder suggests that mood disorders may be related to stressful triggering events (Miklowitz & Alloy, 1999), and perhaps to disturbances in the body's biological clock, which is described in the chapter on consciousness (Goodwin & Jamison, 1990). This second possibility seems especially likely to apply to the 15 percent of depressed people who consistently experience a calendar-linked pattern of depressive episodes known as *seasonal affective disorder (SAD)*. During months of shorter daylight, these people slip into severe depression, accompanied by irritability and excessive sleeping (Blehar & Rosenthal, 1989). Their depression tends to lift as daylight hours lengthen (Faedda et al., 1993). Disruption of biological rhythms is also suggested by the fact that many depressed people tend to have trouble sleeping—perhaps partly because during the day, their biological clocks are telling them it is the middle of the night. Resetting the biological clock through methods such as sleep deprivation or light stimulation has relieved depression in many cases (Kuhs & Tolle, 1991; Terman et al., 2001).

Psychological and Social Factors Researchers have come to recognize that whatever biological causes are involved in mood disorders, their effects are always combined with those of psychological and social causes (U.S. Surgeon General, 1999). As mentioned earlier, the very nature of depressive symptoms can depend on the culture in which a person lives. Biopsychosocial explanations of mood disorders also emphasize the impact of anxiety, negative thinking, and the other psychological and emotional responses triggered by trauma, losses, and other stressful events (Monroe et al., 1999). For example, the higher incidence of depression among females—and especially among poor, ethnic minority, single mothers—has been attributed to their greater exposure to stressors of all kinds (Brown & Moran, 1997; Miranda & Green, 1999). Environmental stressors affect men, too,

which may be one reason why gender differences in depression are smaller in countries where men and women face equally stressful lives (Bierut et al., 1999; Maier et al., 1999). Still, differing stressors may not be the only source of these gender differences (Kendler, Thornton, & Prescott, 2001).

A variety of social-cognitive theories suggest that the way people think about their stressors can increase or decrease the likelihood of mood disorders. One of these theories stemmed from the research on *learned helplessness* described in the chapter on learning. Just as animals become inactive and appear depressed when they have no control over negative events, humans may experience depression as a result of feeling incapable of controlling their lives, especially the stressors confronting them (Klein & Seligman, 1976; Seligman, 1991). But most of us have limited control; why aren't we all depressed? The ways in which people learn to *think* about events in their lives may hold the key. For example, Aaron Beck's (1967, 1976) cognitive theory of depression suggests that depressed people develop mental habits of (1) blaming themselves when things go wrong; (2) focusing on and exaggerating the negative side of events; and (3) jumping to overly generalized, pessimistic conclusions. Such cognitive habits, says Beck, are errors that lead to depressing thoughts and other symptoms of depression (Beck & Beck, 1995). Depressed people, in fact, do think about significant negative events in ways that are likely to increase or prolong their depression (Gotlib & Hammen, 1992).

Social-cognitive theories of depression are somewhat consistent with the psychodynamically oriented *object relations* approach discussed in the chapter on personality (Blatt & Maroudas, 1992). Both views suggest that negative patterns of thinking can be acquired through maladaptive experiences in childhood. For example, research indicates that children whose early relationships with parents or other primary caregivers were characterized by deprivation or abuse are especially likely to develop depression in later life (Gotlib & Hammen, 1992). It may be that close, protective, predictable, and responsive early relationships are necessary if children are to form healthy views of themselves, positive expectations about others, and a sense of control over the environment (Bowlby, 1980; Main, 1996).

Severe, long-lasting depression is especially common among people who attribute the lack of control or other problems they experience to a permanent, generalized personal failing rather than to a temporary lapse or external cause (Seligman et al., 1988). This *attributional style* may be another important cognitive factor in depression (Alloy, Abramson, & Francis, 1999; Ingram, Miranda, & Segal, 1998). People may be prone to depression when they attribute negative events to their own characteristics and believe they will never be capable of doing better. One study of adolescents, for example, found that those who strongly held such dysfunctional attitudes were more likely than other youngsters to develop depression when faced with stress later in life (Lewinsohn, Joiner, & Rohde, 2001).

Depressed people do hold more negative beliefs about themselves and their lives than other people, but the exact significance of these beliefs is not yet clear (Gara et al., 1993). For one thing, pessimistic beliefs may be a symptom of depression rather than its cause. Also, the negative beliefs held by some depressed persons appear to be an accurate reflection of these people's unfortunate life situations and experiences (Coyne & Whiffen, 1995).

In any case, the social-cognitive perspective suggests that whether depression continues or worsens depends in part on how people respond once they start to feel depressed. Those who ruminate, or continuously dwell, on negative events, on why they occur, and even on feeling depressed are likely to feel more and more depressed (Just & Alloy, 1997). According to Susan Nolen-Hoeksema (1990, 2001), this *ruminative style* is especially characteristic of women and may help explain gender differences in the frequency of depression. When men start to feel sad, she says, they tend to use a *distracting style*. That is, they engage in activity that distracts them from their concerns and helps bring them out of their depressed mood (Hankin & Abramson, 2001; Just & Alloy, 1997; Nolen-Hoeksema, Morrow, & Fredrickson, 1993).

Notice that social-cognitive explanations of depression are consistent with the diathesis-stress approach to disorder (Hankin & Abramson, 2001). These explanations suggest that certain cognitive styles constitute a predisposition (or diathesis) that makes a person vulnerable to depression, the occurrence of which is made more likely by stressors. In fact, most episodes of major depressive disorder are preceded by the onset of major stressors, such as the loss of a loved one. As suggested in the chapter on health, stress, and coping, the depressing effects of these stressors are likely to be magnified by lack of social support, inadequate coping skills, and the presence of other stressful conditions such as poverty.

Given the number and complexity of biological, psychological, social, and situational factors potentially involved in causing mood disorders, the biopsychosocial model and the diathesis-stress approach appear to be especially appropriate guides to future research. Studies based on these guides are already bearing fruit. One study looked at the role of genetics and stressful events in shaping mood disorders in a large group of female twin pairs. Both factors were associated with major depression; the women at highest genetic risk were also the most likely to become depressed following a significant stressor (Kendler, Thornton, & Gardner, 2000, 2001). Another study found that among adolescents already at risk for depression because of family history, the ones most likely to actually develop major depressive disorder were those who encountered significant stressors (personal losses and disappointments in the previous month) and who reacted most strongly to stress, as measured by cortisol and other stress-related hormones (Goodyer et al., 2000). In the final analysis, it may turn out that each subtype of mood disorder is caused by a unique combination of factors. The challenge for researchers is to identify these subtypes and map out their causal ingredients.

Schizophrenia

Here is part of a letter that arrived in the mail several years ago:

Dear Sirs:

Pertaining to our continuing failure to prosecute violations of minor's rights to sovereign equality which are occurring in gestations being compromised by the ingestion of controlled substances, . . . the skewing of androgyny which continues in female juveniles even after separation from their mother's has occurred, and as a means of promulflagitating my paying Governor Hickel of Alaska for my employees to have personal services endorsements and controlled substance endorsements, . . . the Iraqi oil being released by the United Nations being identified as Kurdistanian oil, and the July, 1991 issue of the Siberian Review spells President Eltsin's name without a letter y.

The disorganization and bizarre content of this letter suggest that its writer suffers from **schizophrenia** (pronounced "skit-so-FREE-nee-uh"), a pattern of extremely disturbed thinking, emotion, perception, and behavior that seriously impairs the ability to communicate and relate to others and disrupts most other aspects of daily functioning. Schizophrenia is one of the most severe and disabling of all mental disorders. Its core symptoms are seen virtually everywhere in the world, occurring in 1 to 2 percent of the population (American Psychiatric Association, 1994, 2000). In the United States, it appears about equally in various ethnic groups, but like most disorders, it tends to be diagnosed more frequently in economically disadvantaged populations. Schizophrenia is seen about equally in men and women, although in women it may appear later in life, be less severe, and respond better to treatment (American Psychiatric Association, 2000; U.S. Surgeon General, 1999).

schizophrenia A severe and disabling pattern of disturbed thinking, emotion, perception, and behavior.

Schizophrenia tends to develop in adolescence or early adulthood. The onset is gradual in some cases and more rapid in others. About 40 percent of people with schizophrenia improve with treatment and are able to function reasonably well; the rest show continuous or intermittent symptoms that permanently impair their functioning (Hegarty et al., 1994). It has been estimated that 10 to 13 percent of homeless individuals suffer from schizophrenia (Fischer & Breakey, 1991).

One of the best predictors of the course of schizophrenia is *premorbid adjustment*, the level of functioning a person had achieved before schizophrenic symptoms first appeared. Improvement is more likely in those who had attained higher levels of education and occupation, and who had established supportive relationships with family and friends (Watt & Saiz, 1991).

Symptoms of Schizophrenia

People displaying schizophrenia have problems in how they think and what they think. The nineteenth-century psychiatrist Eugen Bleuler coined the word *schizophrenia*, or “split mind,” to refer to the peculiarities of schizophrenic thinking. However, schizophrenia does not mean “split personality,” as in dissociative identity disorder (multiple personality disorder). It refers instead to a splitting of normally integrated mental processes, such as thoughts and feelings. For instance, some schizophrenics may giggle while claiming to feel sad.

Schizophrenic thought and language are often disorganized. *Neologisms* (“new words” that have meaning only to the person speaking them) are common; the appearance of “promulflagitating” in the letter above is one example. That letter also illustrates *loose associations*, the tendency for one thought to be logically unconnected, or only superficially related, to the next. Sometimes the associations are based on double meanings or on the way words sound (*clang associations*). For example, “My true family name is Abel or A Bell. We descended from the clan of Abel, who originated the bell of rights, which we now call the bill of rights.” In the most severe cases, a jumble of words known as *word salad* reflects utterly chaotic thoughts: “Upon the advisability of held keeping, environment of the seabeach gathering, to the forest stream, reinstatement to be placed, poling the paddleboat, of the swamp morass, to the forest compensation of the dunce” (Lehman, 1967, p. 627).

The *content* of schizophrenic thinking is also disturbed. Often it includes a bewildering assortment of delusions, especially delusions of persecution. Some patients claim that space aliens are trying to steal their internal organs, and they may interpret everything from TV commercials to casual hand gestures as part of the plot. Delusions that common events are somehow related to oneself are called *ideas of reference*. *Delusions of grandeur* may also appear; one young man was convinced that the president of the United States was trying to contact him for advice. Other types of delusions include (1) *thought broadcasting*, in which patients believe that their thoughts can be heard by others; (2) *thought blocking* or *withdrawal*, the belief that someone is either preventing thoughts or “stealing” them as they appear; and (3) *thought insertion*, the belief that other people’s thoughts are appearing in one’s own mind. Some patients may believe that their behavior, like a puppet’s, is being controlled by others.

People with schizophrenia often report that they cannot focus their attention. They may feel overwhelmed as they try to attend to everything at once. Various perceptual disorders may also appear. The person may feel detached from the world and see other people as flat cutouts. The body may feel like a machine, or parts of it may seem to be dead or rotting. **Hallucinations**, or false perceptions, are common, often emerging as voices. These voices may sound like an overheard conversation, or they may urge the person to do or not to do things; they may also comment on, narrate, or (most often) harshly criticize the person’s actions or characteristics. Hallucinations can also create sights, smells, tastes, and touches even when no external stimuli are present. (As shown in Figure 15.4, the brain areas activated during hallucinations are

LINKAGES (a link to Cognition and Language)

hallucinations A symptom of disorder in which people perceive voices or other stimuli when there are no stimuli present.

figure 15.4**PET Scan Showing Areas of the Brain Activated During Hallucinations**

This twenty-three-year-old schizophrenic patient hallucinated rolling, disembodied heads that gave him instructions. PET scans revealed heightened activity in the visual and auditory (language) *association* cortex, rather than in the *primary* cortex regions for these senses. Posterior cingulate cortex (part of the limbic system), which was also activated, is known to be affected by drugs that produce hallucinations (Silbersweig et al., 1995).

related to those that respond to real sights and sounds [Shergill et al., 2000].) The emotional expressiveness of people with schizophrenia is often muted, but when they do show emotion, it is frequently exaggerated or inappropriate. They may cry for no apparent reason or fly into a rage in response to a simple question.

Some schizophrenia patients are extremely agitated, ceaselessly moving their limbs, making facial grimaces, or pacing the floor in highly ritualistic sequences. Others become so withdrawn that they move very little. Lack of motivation and poor social skills, deteriorating personal hygiene, and an inability to function day to day are other common characteristics of schizophrenia.

Categorizing Schizophrenia

DSM-IV lists five major subtypes of schizophrenia: paranoid, disorganized, catatonic, undifferentiated, and residual (see Table 15.4). These subtype labels convey a certain amount of useful information. We know, for example, that the prognosis for paranoid schizophrenia is somewhat better than for the other subtypes (Fenton & McGlashan, 1991). However, subtype labels do not always provide accurate information about patients' behavior, because some symptoms appear in more than one subtype. Further, people originally diagnosed as suffering from disorganized schizophrenia might later display characteristics of the paranoid subtype. Finally, the DSM-IV subtypes may not be linked very closely to the various biological conditions thought to underlie schizophrenia (Fenton & McGlashan, 1991). With these concerns in mind, many researchers are now using methods of categorizing schizophrenia that focus more precisely on the kinds of symptoms that patients display.

One such method highlights the positive-negative symptom dimension in schizophrenia. Disorganized thoughts, delusions, and hallucinations are sometimes called

Mental health professionals still use these *DSM-IV* subtypes when diagnosing schizophrenia, but many researchers now tend to categorize patients in terms of whether positive or negative symptoms of schizophrenia predominate in a given case.

table 15.4
Subtypes of Schizophrenia

Type	Frequency	Prominent Features
Paranoid schizophrenia	40 percent of schizophrenics; appears late in life (after age 25–30)	Delusions of grandeur or persecution; anger; anxiety; argumentativeness; extreme jealousy; onset often sudden; signs of impairment may be subtle.
Disorganized schizophrenia	5 percent of all schizophrenics; high prevalence in homeless population	Delusions; hallucinations; incoherent speech; facial grimaces; inappropriate laughter/giggling; neglected personal hygiene; loss of bladder/bowel control.
Catatonic schizophrenia	8 percent of all schizophrenics	Disordered movement, alternating between total immobility (stupor) and wild excitement. In stupor, the person does not speak or attend to communication; also, the body is rigid or can be posed in virtually any posture (a condition called <i>waxy flexibility</i>).
Undifferentiated schizophrenia	40 percent of all schizophrenics	Patterns of disordered behavior, thought, and emotion that do not fall easily into any other subtype.
Residual schizophrenia	Varies	Applies to people who have had prior episodes of schizophrenia but are not currently displaying symptoms.

positive symptoms of schizophrenia, because they appear as undesirable *additions* to a person's mental life (Andreasen et al., 1995). In contrast, the absence of pleasure and motivation, lack of emotional reactivity, social withdrawal, reduced speech, and other deficits seen in schizophrenia are sometimes called **negative symptoms**, because they appear to *subtract* elements from normal mental life (Nicholson & Neufeld, 1993).

Describing patients in terms of positive and negative symptoms does not require that they be placed in one category or the other. In fact, many patients exhibit both positive and negative symptoms. However, it is important to know whether negative or positive symptoms predominate, because when symptoms are mainly negative, schizophrenia is generally more severe and less responsive to treatment. In such cases, patients typically experience long-term disability (e.g., Fenton & McGlashan, 1994).

Another way of categorizing schizophrenic symptoms focuses on whether they are *psychotic* (hallucinations, delusions), *disorganized* (incoherent speech, chaotic behavior, inappropriate affect), or *negative* (e.g., lack of speech or motivation). Some researchers believe that these categories of symptoms represent three separate dimensions of schizophrenia (Buchanan & Carpenter, 1994; Grube, Bilder, & Goldman,

positive symptoms Schizophrenic symptoms such as disorganized thoughts, hallucinations, and delusions.

negative symptoms Schizophrenic symptoms such as absence of pleasure, lack of speech, and flat affect.

Catatonic Stupor The symptoms of schizophrenia often occur in characteristic patterns. This woman's lack of motivation and other negative symptoms of schizophrenia are severe enough that she appears to be in a stupor. Such patients may become rigid or, as in this case, show a waxy flexibility that allows them to be posed in virtually any position. Diagnosticians using the traditional subtype system would probably label her as displaying catatonic schizophrenia.

1998; Johnstone & Frith, 1996). Not all studies have supported this interpretation (Dudgeon et al., 2001), but some research shows that patients' negative symptoms remain stable, and may even worsen, at the same time that their psychotic symptoms are being reduced through drug treatment (Andreasen et al., 1995).

The fact that, like positive and negative symptoms, the three dimensions of schizophrenia are to some extent independent from one another suggests to some researchers that each symptom cluster or dimension may ultimately be traceable to different causes, and that each may require different treatments (Tsuang, Stone, & Faraone, 2000).

Causes of Schizophrenia

The search for the causes of schizophrenia has been more intense than for any other psychological disorder. The findings so far confirm one thing for certain: As with other disorders, there are biological, psychological, and social factors at work in causing or worsening all forms of schizophrenia (U.S. Surgeon General, 1999).

Biological Factors Research in behavioral genetics shows that schizophrenia runs in families (Asarnow et al., 2001; Gottesman, 1991). One longitudinal family study found, for instance, that 16 percent of the children of schizophrenic mothers—compared with 2 percent of those of nonschizophrenic mothers—developed schizophrenia themselves over a twenty-five-year period (Parnas et al., 1993). Even if they are adopted by nonschizophrenic families, the children of schizophrenic parents are ten times more likely to develop schizophrenia than adopted children whose biological parents are not schizophrenic (Kety et al., 1994). Still, it is unlikely that a single gene transmits schizophrenia (Kendler & Diehl, 1993). Among identical-twin pairs in which one member displays schizophrenia, 40 percent of the other members will, too; but 60 percent will not (McGue, 1992). It is more likely that some people inherit a genetic predisposition, or diathesis, for schizophrenia that then combines with other genetic and nongenetic factors to cause the disorder (Moldin & Gottesman, 1997).

The search for these more specific causes of schizophrenia focuses on a number of abnormalities in the structure, functioning, and chemistry of the brain that tend to appear in schizophrenics. For example, numerous brain imaging studies have shown that, compared with other mental patients, many schizophrenia patients have less tissue in thalamic regions, prefrontal cortex, and some subcortical areas (Baare et al., 2001; Byne et al., 2001; Gilbert et al., 2001; Pol et al., 2002; Sigmundsson et al., 2001). As shown in Figure 15.5, shrinkage of tissue in these regions leads to corresponding enlargement in the brain's fluid-filled spaces, called *ventricles*. The brain areas in which anatomical abnormalities have been found are active in emotional expression, thinking, and information processing—functions that are disordered in schizophrenia. Enlarged ventricles and reduced prefrontal cortex are more often found in patients whose schizophrenic symptoms are predominantly negative (Sigmundsson et al., 2001), and in one study, faster shrinkage appeared associated with more severe negative symptoms (Mathalon et al., 2001). Patients with mainly positive symptoms tend to have essentially normal looking brains (Andreasen, 1997).

Hundreds of studies of brain functioning in people diagnosed with schizophrenia provide general support for the idea that their impairments in information processing and other cognitive abilities are consistent with structural damage (Clementz, McDowell, & Zisook, 1994; Gur et al., 2000; Niznikiewicz et al., 1997). For example, patients with predominantly negative symptoms are especially likely to display cognitive deficits associated with the frontal-cortex problems often seen in these patients (Buchanan et al., 1994). This research provides important clues, but we still do not know the extent to which, or exactly how, specific structural abnormalities are related to the differing patterns of neurocognitive dysfunction seen in specific forms of schizophrenia (Allen, Goldstein, & Weiner, 2001). For one

figure 15.5**Brain Abnormalities in Schizophrenia**

Here is a magnetic resonance imaging (MRI) comparison of the brains of identical twins. The schizophrenic twin (on the right) has greatly enlarged ventricles (see arrows) and correspondingly less brain tissue, including in the hippocampal area, a region involved in memory and emotion. The same results appeared in fourteen other identical-twin pairs; by contrast, no significant differences appeared between members of a seven-pair control group of normal identical twins (Suddath et al., 1990). These results support the idea that brain abnormalities are associated with schizophrenia and, because identical twins have the same genes, that such abnormalities may stem from nongenetic factors (Baare et al., 2001).

thing, not all schizophrenia patients show brain abnormalities, and some normal people do.

Researchers are also investigating the possibility that abnormalities in brain chemistry—especially in neurotransmitter systems that use dopamine—play a role in causing or intensifying schizophrenic symptoms. Because drugs that block the brain's dopamine receptors often reduce hallucinations, delusions, disordered thinking, and other positive symptoms of schizophrenia, some investigators speculate that schizophrenia results from excess dopamine. However, the relationship between dopamine and schizophrenia appears to be quite complex in several respects (Healy et al., 1998). First, excess dopamine is not always associated with schizophrenia. Second, schizophrenia may involve oversensitivity or undersensitivity of dopamine receptors, as well as an abnormal amount of dopamine itself. And third, schizophrenia might be related to *dysregulation* of dopamine mechanisms in several interconnected regions of the brain (e.g., Healy et al., 1998). Some research suggests, for example, that excessive activity in dopamine systems may be related to the appearance of hallucinations and other positive symptoms of schizophrenia, and that abnormally low dopamine system activity, especially in prefrontal brain areas, might be associated with negative symptoms such as withdrawal (Cohen & Servan-Schreiber, 1992; Davis et al., 1991). Negative symptoms have also been associated with dysfunctions in neural systems that use the neurotransmitter glutamate (Goff & Coyle, 2001).

Some researchers are integrating genetic and environmental explanations of schizophrenia by looking for *neurodevelopmental abnormalities* (Cannon et al., 2002; Gur et al., 2000; Loeber, Cintron, & Yurgelun-Todd, 2001; McGlashan & Hoffman, 2000; Walbeck et al., 2001). Perhaps, they say, some forms of schizophrenia arise from disruptions in brain development during the period from gestation through childhood, when the brain is growing and its various functions are maturing. Studies have shown, for instance, that prenatal exposure to viral infections or other physical traumas is associated with increased risk for developing schizophrenia (Malaspina et al., 2001; Takei et al., 1994). Similarly, children whose birth weight was low or who experienced oxygen deprivation during birth are more likely to have the brain abnormalities described earlier; these abnormalities are especially likely in children of schizophrenic parents (Cannon et al., 1993; Lawrie et al., 2001). Neurodevelopmental factors may help explain why children of schizophrenic parents tend to show the kinds of subtle cognitive and intellectual problems

associated with brain abnormalities (Ashe, Berry, & Boulton, 2001; Cannon et al., 1994; McGlashan & Hoffman, 2000; Neumann et al., 1995).

It may be that the expression of a genetically transmitted predisposition for brain abnormality is also enhanced by environmental factors such as maternal drug use during pregnancy, complications during birth, and childhood malnutrition. As mentioned earlier, for example, the development of smaller-than-normal frontal lobes and other brain structures appears to constitute an inherited predisposition for schizophrenia. However, reduced brain growth alone does not appear to be sufficient to cause the disorder. Recent research shows that when only one member of an identical twin pair has schizophrenia, both tend to have unusually small brains, but that the schizophrenic twin's brain in each pair is the smaller of the two (Baare et al., 2001). This finding suggests that some environmentally based process caused degeneration in an already underdeveloped brain, making it even more prone to function abnormally.

Psychological and Social Factors Psychological factors alone are not considered to be primary causes of schizophrenia. Research does suggest, however, that psychological and social processes, including unfortunate learning experiences, dysfunctional cognitive habits, and maladaptive family communication patterns, can contribute to the appearance of schizophrenia and influence its course (Blackwood et al., 2001; Pitschel-Walz et al., 2001). For example, schizophrenia patients living with relatives who are critical, unsupportive, or emotionally overinvolved are especially likely to relapse following improvement (Rosenfarb et al., 2000; Wearden et al., 2000). Family members' negative attitudes may be a source of stress that actually increases the chances that disruptive or odd behaviors will persist or worsen (Rosenfarb et al., 1995). Patients who are helped to cope with these potentially damaging influences tend to have better long-term outcomes (Bustillo et al., 2001; Velligan et al., 2000).

Vulnerability Theory All the causal theories of schizophrenia we have discussed are consistent with the diathesis-stress approach, which assumes that various forms of stress can activate a person's predisposition for disorder (Fowles, 1992). ("In Review: Schizophrenia" summarizes these theories, as well as the symptoms of schizophrenia.) The diathesis-stress approach is embodied in the *vulnerability theory* of schizophrenia (Cornblatt & Erlenmeyer-Kimling, 1985). This theory suggests that (1) vulnerability to schizophrenia is mainly biological; (2) different people have differing degrees of vulnerability; (3) vulnerability is influenced partly by genetic influences on development and partly by neurodevelopmental abnormalities associated with environmental risk factors; and (4) psychological components—such as exposure to poor parenting or high-stress families, having inadequate coping skills, and the like—may help determine whether schizophrenia actually appears and also influence the course of the disorder (Walker & Diforio, 1998; Wearden et al., 2000).

Many different blendings of vulnerability and stress can lead to schizophrenia, as Figure 15.6 illustrates. People whose genetic characteristics or prenatal experiences leave them vulnerable to develop schizophrenia may be especially likely to do so if they are later exposed to learning experiences or family conflicts and other stressors that trigger and maintain schizophrenic patterns of thought and action. Those same experiences and stressors would not be expected to lead to schizophrenia in people who are less vulnerable to developing the disorder. In other words, schizophrenia is a highly complex disorder—probably more than one disorder (Kirkpatrick et al., 2001; Tsuang, Stone, & Faraone, 2000) whose origins appear to lie in numerous biological, psychological, and social domains, some of which are yet to be discovered (Thaker & Carpenter, 2001).

figure 15.6

The Vulnerability Theory of Schizophrenia

According to vulnerability theory, a person can cross the threshold into schizophrenia through many combinations of predisposition and stress. A strong predisposition for schizophrenia and little environmental stress (point D), a weak predisposition and a lot of stress (point C), or any other sufficiently potent combination can lead to the disorder. Points A and B represent combinations of vulnerability and stress that would probably not lead to schizophrenia.

in review Schizophrenia

Aspect	Key Features
Common Symptoms	
Disorders of thought	Disturbed content, including delusions; disorganization, including loose associations, neologisms, and word salad
Disorders of perception	Hallucinations, or false perceptions; poorly focused attention
Disorders of emotion	Flat affect; inappropriate tears, laughter, or anger
Possible Causes	
Biological	Genetics; abnormalities in brain structure; abnormalities in dopamine systems; neurodevelopmental problems
Psychological	Learned maladaptive behavior; disturbed patterns of family communication

Personality Disorders

Personality disorders are long-standing, inflexible ways of behaving that are not so much severe mental disorders as dysfunctional styles of behavior. These disorders affect all areas of functioning and, beginning in childhood or adolescence, create problems for those who display them and for others (Millon & Davis, 1996). Some psychologists view personality disorders as interpersonal strategies (Kiesler, 1996) or as the extreme, rigid, and maladaptive expressions of personality traits (Widiger, 1997).

The ten personality disorders found on Axis II of *DSM-IV* are grouped into three clusters that share certain features (see Table 15.5). Here, we describe just a few of these disorders. The *odd-eccentric* cluster includes paranoid, schizoid, and schizotypal personality disorders. People diagnosed as having schizotypal personality disorder, for example, display some of the peculiarities seen in schizophrenia but are not disturbed enough to be labeled as schizophrenic. Rather than hallucinating, these people may report “illusions” of sights or sounds. They may also exhibit “magical thinking,” including odd superstitions or beliefs (such as that they have extrasensory perception or that salt under the mattress will prevent insomnia). The *anxious-fearful* cluster includes dependent, obsessive-compulsive, and avoidant personality disorders. The avoidant personality disorder, for example, is akin to social phobia in the sense that persons labeled with this disorder tend to be “loners” with a long-standing pattern of avoiding social situations and of being particularly sensitive to criticism or rejection. They want to be with others but are too inhibited. Finally, the *dramatic-erratic* cluster includes the histrionic, narcissistic, borderline, and antisocial personality disorders. The main characteristics of narcissistic personality disorder, for example, are an exaggerated sense of self-importance, extreme sensitivity to criticism, a constant need for attention, and a tendency to arrogantly overestimate personal abilities and achievements. People displaying this disorder feel entitled to special treatment by others but are markedly lacking in empathy for others.

From the perspective of public welfare and safety, the most serious, costly, and intensively studied personality disorder is **antisocial personality disorder** (e.g., Scott et al., 2001). It is marked by a long-term pattern of irresponsible, impulsive, unscrupulous, even criminal behavior beginning in childhood or early adolescence. In the nineteenth century, this pattern was called *moral insanity*, because the people displaying it appear to have no morals or common decency; later, these people were

personality disorders Long-standing, inflexible ways of behaving that create a variety of problems.

antisocial personality disorder A disorder involving impulsive, selfish, unscrupulous, even criminal behavior.

Here are brief descriptions of the ten personality disorders listed on Axis II of *DSM-IV*.

table 15.5
Personality Disorders

Type	Typical Features
Paranoid	Suspiciousness and distrust of others, all of whom are assumed to be hostile.
Schizoid	Detachment from social relationships; restricted range of emotion.
Schizotypal	Detachment from, and great discomfort in, social relationships; odd perceptions, thoughts, beliefs, and behaviors.
Dependent	Helplessness; excessive need to be taken care of; submissive and clinging behavior; difficulty in making decisions.
Obsessive-compulsive	Preoccupation with orderliness, perfection, and control.
Avoidant	Inhibition in social situations; feelings of inadequacy; oversensitivity to criticism.
Histrionic	Excessive emotionality and preoccupation with being the center of attention; emotional shallowness; overly dramatic behavior.
Narcissistic	Exaggerated ideas of self-importance and achievements; preoccupation with fantasies of success; arrogance.
Borderline	Lack of stability in interpersonal relationships, self-image, and emotion; impulsivity; angry outbursts; intense fear of abandonment; recurring suicidal gestures.
Antisocial	Shameless disregard for, and violation of, other people's rights.

called *psychopaths* or *sociopaths*. The current “antisocial personality” label more accurately portrays them as troublesome but not “insane” by the legal standards we will discuss shortly. About 3 percent of men and about 1 percent of women in the United States fall into this diagnostic category (American Psychiatric Association, 1994, 2000).

At their least troublesome, people exhibiting antisocial personality disorder are a nuisance. They are often charming, intelligent, glib talkers who borrow money and fail to return it; they are arrogant and self-centered manipulators who con people into doing things for them, usually by lying and taking advantage of the decency and trust of others. A hallmark of people with antisocial personality disorder is a lack of anxiety, remorse, or guilt, whether they have wrecked a borrowed car or killed an innocent person (Hare, 1993). Fortunately, these individuals tend to become less active and dangerous after the age of forty (Stoff, Breiling, & Maser, 1997). No method has yet been found for permanently altering their behavior (Rice, 1997), but research suggests that identification of antisocial personalities prior to the development of their more treatment-resistant traits may offer the best hope for dealing with this disorder (Lynam, 1996; Stoff, Breiling, & Maser, 1997).

As for the causes of antisocial personality disorder, theories abound. Some studies suggest a genetic predisposition for the disorder (Slutske et al., 2001), possibly in the form of abnormal brain development or chronic underarousal of both the autonomic and central nervous systems (Patrick, Cuthbert, & Lang, 1994; Raine, Venables, & Williams, 1990; Raine et al., 2000). This underarousal may render peo-

A Classic Case of Antisocial Personality Disorder

Alfred Jack Oakley meets women through personals ads, claiming to be a millionaire movie producer, pilot, and novelist. In reality, he is a penniless con artist who uses his smooth-talking charm to gain the women's trust so he can steal from them. In January 2000, upon being convicted of stealing a Florida woman's Mercedes, Oakley complimented the prosecutor's skills and the jury's wisdom, and claimed remorse. The judge appeared to see through this ploy ("I don't believe there is a sincere word that ever comes out of your mouth"), but it was still effective enough to get Oakley probation instead of jail time!

ple less sensitive to punishment and more likely to seek exciting stimulation than is normally the case (Herpertz et al., 2001; Stoff, Breiling, & Maser, 1997). Broken homes, rejection by parents, poor discipline, lack of good parental models, lack of attachment to early caregivers, impulsivity, conflict-filled childhoods, and poverty have all been suggested as psychological and social factors contributing to the development of antisocial personality disorder (Lahey et al., 1995; Raine, Brennan, & Mednick, 1994; Tremblay et al., 1994). The biopsychosocial model suggests that antisocial personality disorder results when these psychosocial and environmental conditions interact with genetic predispositions to low arousal and the sensation seeking and impulsivity associated with it (Rutter, 1997).

FOCUS ON RESEARCH METHODS

Exploring Links Between Child Abuse and Antisocial Personality Disorder

One of the most prominent environmental factors associated with the more violent forms of antisocial personality disorder is the experience of abuse in childhood (MacMillan et al., 2001). However, most of the studies that have found a relationship between childhood abuse and antisocial personality disorder were based on potentially biased reports (Monane, Leichter, & Lewis, 1984; Rosenbaum & Bennett, 1986). People with antisocial personalities—especially those with criminal records—are likely to make up stories of abuse in order to shift blame for their behavior onto others. Even if these people's reports were accurate, however, most of the studies lacked a control group of people from similar backgrounds who were not antisocial. Because of this research design flaw, it is virtually impossible to separate the effects of reported child abuse from the effects of poverty or other factors that might also have contributed to the development of antisocial personality disorder.

● What was the researcher's question?

Can childhood abuse cause antisocial personality disorder? To help answer this question and to correct some of the flaws in earlier studies, Cathy Widom (1989a)

used a prospective research design, first finding cases of childhood abuse and then looking for the effects of that abuse on adult behavior.

● **How did the researcher answer the question?**

Widom began by identifying 416 adults whose backgrounds included official records of having been physically or sexually abused before the age of eleven. She then explored the stories of these people's lives, as told in police and school records, as well as in two-hour diagnostic interviews. To reduce experimenter bias and distorted reporting, Widom ensured that the interviewers remained "blind" to the purpose of the study and that the respondents were told only that the researchers wanted to learn about people who had grown up in a midwestern U.S. metropolitan area in the late 1960s and early 1970s. Widom also selected a comparison group of 283 people who had no history of abuse, but who were similar to the abused sample in terms of age, gender, ethnicity, hospital of birth, schools attended, and area of residence. Her goal was to obtain a nonabused control group that had been exposed to approximately the same environmental risk factors and socioeconomic conditions as the abused children.

● **What did the researcher find?**

First, Widom (1989a) tested the hypothesis that exposure to abuse in childhood is associated with criminality and/or violence in later life. She found that 26 percent of the abused youngsters went on to commit juvenile crimes, 29 percent were arrested as adults, and 11 percent committed violent crimes. These percentages were significantly higher than the figures for the nonabused group. The association between criminality and abuse was stronger for males than for females, and stronger for African Americans than for European Americans. And overall, victims of physical abuse were more likely to commit violent crimes as adults than were victims of sexual abuse.

Next, Widom tested the hypothesis that childhood abuse is associated with the development of antisocial personality disorder (Luntz & Widom, 1994). In fact, the abused group exhibited a significantly higher rate of antisocial personality disorder (13.5 percent) than did the comparison group (7.1 percent). The apparent role of abuse in antisocial personality disorder was particularly pronounced in men, and it remained strong even when other factors—such as age, ethnicity, and socioeconomic status—were accounted for in the statistical analyses. It is interesting to note that one other factor—failure to graduate from high school—was also strongly associated with the appearance of antisocial personality disorder, whether or not childhood abuse had occurred.

● **What do the results mean?**

Widom's research supported earlier studies in finding an association between childhood abuse and criminality, violence, and antisocial personality disorder. Further, although her study did not permit a firm conclusion that abuse alone causes antisocial personality disorder, the data from its prospective design added strength to the argument that abuse may be an important causal factor (Widom, 2000). The results suggest that there are probably other causes as well. For one thing, abuse is often part of a larger pool of experiences, such as exposure to deviant models, social rejection, poor supervision, and the like.

Finally, Widom's work offers yet another reason—as if more reasons were needed—why it is so important to prevent the physical and sexual abuse of children. The long-term consequences of such abuse can be tragic not only for its immediate victims but also for those victimized by the violence, criminal actions, and antisocial behavior perpetrated by some abused children as they grow up (Weiler & Widom, 1996).

● **What do we still need to know?**

Further research is needed to discover whether antisocial personality disorder stems from abuse itself, from one of the factors accompanying it, or from some other specific combination of known and still-unknown risk factors. For example,

Widom's study suggests that one or more of the factors leading teenagers to drop out (or be thrown out) of high school might be an independent cause of antisocial personality disorder.

In addition, because Widom's study found that violence, criminal behavior, and antisocial personality disorder are seen in only a minority of abused children, her results raise the question of what genetic characteristics or environmental experiences serve to protect some children from at least some of the devastating effects of abuse (Rind & Tromovitch, 1997; Rind, Tromovitch, & Bauserman, 1998). An understanding of these protective elements might go a long way toward the development of programs for the prevention of antisocial personality disorder.

A Sampling of Other Psychological Disorders

The disorders described so far represent some of the most prevalent and socially disruptive psychological problems encountered in cultures around the world. Several others are mentioned in other chapters. In the chapter on consciousness, for example, we discuss insomnia, night terrors, and other sleep disorders; mental retardation is covered in the chapter on cognitive abilities; sexual dysfunctions are mentioned in the chapter on motivation and emotion; and posttraumatic stress disorder is described in the chapter on health, stress, and coping. Here, we consider two other significant psychological problems: disorders of childhood and substance-related disorders.

Psychological Disorders of Childhood

The physical, cognitive, emotional, and social changes seen in childhood—and the stress associated with them—can create or worsen psychological disorders in children. Stress can do the same in adults, but childhood disorders are not just miniature versions of adult psychopathology. Because children's development is still incomplete and because their capacity to cope with stress is limited, children are often vulnerable to special types of disorders. Two broad categories encompass the majority of childhood behavior problems: externalizing disorders and internalizing disorders (Achenbach, 1997; Nigg, 2000).

The *externalizing*, or *undercontrolled*, category includes behaviors that are particularly disturbing to people in the child's environment. Lack of control shows up as *conduct disorders* in 4 to 10 percent of children, mostly boys (Martin & Hoffman, 1990). Conduct disorders are characterized by a relatively stable pattern of aggression, disobedience, destructiveness, and other problematic behaviors (Lahey et al., 1995). Often these behaviors involve criminal activity, and they may signal the development of antisocial personality disorder (Loeber & Stouthamer-Loeber, 1998). A genetic predisposition toward conduct disorders is suggested by the fact that many such children have parents who display antisocial personality disorder. There is no doubt, however, that environmental and parenting factors also help to shape these children's antisocial behavior (Lahey et al., 1995; U.S. Surgeon General, 1999).

Another kind of externalizing problem, also seen primarily in boys, is *attention deficit hyperactivity disorder (ADHD)*. This diagnosis is given to children who are impulsive and unable to concentrate on an activity as well as other children their age can (Nigg, 2001). Many of these children are *hyperactive*; they have great difficulty sitting still or otherwise controlling their physical activity. Their impulsiveness and lack of self-control contribute to significant impairments in learning, and to an astonishing ability to annoy and exhaust those around them (Henker & Whalen, 1989). Genetic predisposition, brain damage, poisoning from lead or other household substances, and ineffective parenting have all been proposed as possible causes

TRY THIS

Active or Hyperactive?

Normal behavior for children in one culture might be considered hyperactive in other cultures. Do people in the *same* culture disagree on what is hyperactive? To find out, ask two or three friends to join you in observing a group of children at a playground, a schoolyard, a park, or some other public place. Ask your friends to privately identify which children they would label as “hyperactive,” and then count how many of their choices agree with yours and with the rest of the group.

of ADHD, but the role played by each of these factors is still uncertain (Daly et al., 1999; U.S. Surgeon General, 1999). Also uncertain is exactly what constitutes hyperactivity (Panksepp, 1998). Cultural standards about acceptable activity levels in children vary, so a “hyperactive” child in one culture might be considered merely “active” in another. In fact, when mental health professionals from four cultures used the same rating scales to judge the presence and severity of hyperactivity in a videotaped sample of children’s behavior, the Chinese and Indonesians rated the children as significantly more hyperactive than did their American and Japanese colleagues (Mann et al., 1992). Such findings remind us again that sociocultural factors can be important determinants of what is acceptable, and thus what is abnormal, in various parts of the world.

A second group of child behavior problems falls into the *internalizing*, or *over-controlled*, category. Children in this category experience distress, especially depression and anxiety, and may be socially withdrawn. Those displaying *separation anxiety disorder*, for example, constantly worry that they will be lost, kidnapped, or injured or that some harm may come to a parent (usually the mother). The child clings desperately to the parent and becomes upset or sick at the prospect of any separation. Refusal to go to school (sometimes called “school phobia”) is often the result.

A few childhood disorders, such as *pervasive developmental disorders*, do not fall into either the externalizing or internalizing category. Children diagnosed with these disorders show severe deficits in communication and impaired social relationships; they also often display repetitive, stereotyped behaviors and unusual preoccupations and interests (American Psychiatric Association, 2000; Filipek et al., 1999). The disorders in this group, also known as *autistic spectrum disorders* (Filipek et al., 1999; Rutter & Schopler, 1992; U.S. Surgeon General, 1999), share many of these core symptoms, although the severity of the symptoms may vary. Estimates of the prevalence of autistic spectrum disorders range from 10 to 20 children per 10,000 births (Bryson & Smith, 1998; Filipek et al., 1999) to as high as 62 per 10,000 (Chakrabarti & Fombonne, 2001). About half of these children suffer *autistic disorder*, which can be the most severe disorder of the group. The earliest

signs of autistic disorder usually occur within the first thirty months after birth, as these babies show little or no evidence of forming an attachment to their caregivers. Language development is seriously disrupted in most of these children; half of them never learn to speak at all. However, those who display high functioning autism or a less severe autistic spectrum disorder called *Asperger's disorder* are able to function adaptively and, in some cases, independently as adults (e.g., Grandin, 1996).

Possible biological roots of autistic disorder include genetic factors (Burac, 2001; Vastag, 2001) or neurodevelopmental abnormalities affecting language and communication (Courchesne et al., 2001; U.S. Surgeon General, 1999). The more specific causes of autistic disorder remain unknown, but it is likely that genetic influences, along with prenatal damage leading to structural brain abnormalities, are involved (Carper & Courchesne, 2000; Juul-Dam, Townsend, & Courchesne, 2001; Rodier, 2000; Szatmari et al., 1998; U.S. Surgeon General, 1999). Researchers today have rejected the once-popular hypothesis that autistic disorder is caused by cold and unresponsive parents.

Disorders of childhood differ from adult disorders not only because the patterns of behavior are distinct but also because their early onset renders childhood disorders especially capable of disrupting development. To take one example, children whose separation anxiety causes spotty school attendance may not only fall behind academically but also fail to form the relationships with other children that promote normal social development. Some children never make up for this deficit. They may drop out of school and risk a life of poverty, crime, and violence. Moreover, children are dependent on others to obtain help for their psychological problems, and all too often those problems may go unrecognized or untreated. For some, the long-term result may be adult forms of mental disorder.

Substance-Related Disorders

Childhood disorders, especially externalizing disorders, often lead to **substance-related disorders** in adolescence and adulthood. *DSM-IV* defines *substance-related disorders* as the use of psychoactive drugs for months or years in ways that harm the user or others. These disorders create major political, economic, social, and health problems worldwide. The substances involved most often are alcohol and other depressants (such as barbiturates), opiates (such as heroin), stimulants (such as cocaine or amphetamines), and hallucinogens (such as LSD).

As mentioned in the chapter on consciousness, one effect of using some substances (including alcohol, heroin, and amphetamines) is **addiction**, a physical need for the substance. *DSM-IV* calls addiction *physiological dependence*. Usually, addiction is evident when the person begins to need more and more of a substance to achieve the desired state; this is called building a *tolerance*. When addicted people stop using the substance, they experience painful, often terrifying, and potentially dangerous *withdrawal symptoms* as the body tries to readjust to a substance-free state. However, not all dependence is physiological in nature (Widiger & Smith, 1994). People can also display *psychological dependence*, sometimes called *behavioral dependence*; in such cases, a drug has become their primary source of reward, and their lives essentially revolve around getting and using it. People who are psychologically dependent on a drug often display problems that are at least as serious as, and sometimes more difficult to treat than, those exhibited by people who are physiologically addicted.

Even when use of a drug does not create psychological or physiological dependence, some people may use it in a way that is harmful to themselves or others. For example, they may rely on the drug to bolster self-confidence or to avoid depression, anger, fear, or other unpleasant feelings. However, the drug effects these people seek may also impair their ability to hold a job, care for their children, or drive safely. This pattern of behavior, defined in *DSM-IV* as *substance abuse*, creates significant social, legal, and interpersonal problems.

substance-related disorders Problems that involve the use of psychoactive drugs for months or years in ways that harm the user or others.

addiction The development of a physical need for a psychoactive drug.

In short, substance-related disorders can be extremely serious, even when they do not involve addiction. The chapter on consciousness includes a discussion of how consciousness can be affected by a wide range of psychoactive drugs. Here we focus more specifically on problems associated with the use of alcohol, heroin, and cocaine.

Alcohol Use Disorders About 7.4 percent of U.S. adults—about 14 million people—display *alcohol dependence* or *alcohol abuse*, a pattern of continuous or intermittent drinking that may lead to addiction and almost always causes severe social, physical, and other problems (National Institute on Alcohol Abuse and Alcoholism, 2000). Males outnumber females in this category by a ratio of about three to one, although the problem is on the rise among women and among teenagers of both genders (Blum, Nielsen, & Riggs, 1998; U.S. Surgeon General, 1999). Prolonged overuse of alcohol can result in life-threatening liver damage, reduced cognitive abilities, vitamin deficiencies that can lead to an irreversible brain disorder called *Korsakoff's psychosis* (severe memory loss), and a host of other physical ailments. Many of these adverse effects appear to be due to the fact that excessive alcohol consumption causes deterioration in several brain areas (Hommer et al., 2001; Pfefferbaum et al., 2001).

Alcohol dependence or abuse, commonly referred to as **alcoholism**, has been implicated in half of all the traffic fatalities, homicides, and suicides that occur each year (NIAAA, 1998). Alcoholism also figures prominently in rape and child abuse, as well as in elevated rates of hospitalization and absenteeism from work, resulting in total costs to society of over \$180 billion each year (Harwood, Fountain, & Livermore, 1998; NIAAA, 2000; U.S. Department of Justice, 1998). It is estimated that about half of U.S. adults have a close relative who is or was an alcoholic, and that about 25 percent of children are exposed to adults who display alcohol abuse or dependence (NIAAA, 2000). Children growing up in families in which one or both parents abuse alcohol are at increased risk for developing a host of mental disorders, including substance-abuse disorders (Sher et al., 1991). And, as described in the chapter on human development, children of mothers who abused alcohol during pregnancy may be born with fetal alcohol syndrome.

The biopsychosocial model suggests that alcohol use disorders stem from a combination of genetic characteristics (including inherited aspects of temperament such as impulsivity and emotionality) and what people learn in their social and cultural environment (Petry, 2001; Sher et al., 1991; Wall et al., 2001). For example, youngsters typically learn to drink by watching others (especially their friends), and by developing expectations that alcohol will make them feel good and help them cope with stressors (Koopmans & Boomsma, 1996). But alcohol use can become abuse, and often addiction, if drinking is a person's main coping strategy (NIAAA, 2000; see Table 15.6). The stress-reduction theory of alcoholism has been supported by studies showing that alcohol can reduce animals' learned fear of a particular location and that animals in a stressful conflict situation will choose to drink alcohol if it is available. The stress-reducing effects of alcohol have also been shown in humans, but not consistently (Burke & Stephens, 2000; Cooper et al., 1992a).

The importance of social and cultural learning is further suggested by evidence that alcoholism is more common among ethnic and cultural groups (such as the Irish and English) in which frequent drinking tends to be socially reinforced than among groups (such as Jews, Italians, and Chinese) in which all but moderate drinking tends to be discouraged (Wilson et al., 1996). Moreover, differing expressions of social support for drinking can result in differing consumption patterns within a cultural group. For example, one study found significantly more drinking among Japanese men living in Japan (where social norms for males' drinking are quite permissive) compared with those living in Hawaii or California, where excessive drinking is less strongly supported (Kitano et al., 1992). Learning would also help explain why the incidence of alcoholism is higher than average among people working as

alcoholism A pattern of drinking that may lead to addiction and almost always causes severe social, physical, and other problems.

Social drinking differs markedly from alcoholism, but it is all too easy for people to drift from social to alcoholic drinking patterns. Alcoholism can include heavy drinking on a daily basis, on weekends only, or in isolated binges lasting weeks or months (NIAAA, 2000).

table 15.6
Social Drinking Versus Alcoholism

Social Drinkers	Alcoholics
Sip drinks	Gulp drinks.
Usually drink in moderation and can control the amount consumed.	Drink increasing quantities (develop tolerance); sometimes drink until blacking out; may not recall events that occur while drinking.
Usually drink to enhance the pleasure of social situations.	Drink for the chemical effect, often to relieve tension or face problems; often drink alone, including in the morning to reduce hangover or to face the day.
Do not usually think about or talk about drinking in nondrinking situations.	Become preoccupied with getting their next drink, often sneaking drinks during working hours or at home.
Do not experience physical, social, or occupational problems caused by drinking.	Suffer physical disorders, damaged social relationships, and impaired capacity to work because of drinking.

bartenders and cocktail servers, as well as in other jobs where alcohol is available and drinking is socially reinforced, or even expected (Fillmore & Caetano, 1980). (Of course, it is also possible that attraction to alcohol led some of these people into such jobs in the first place.)

Learning, then, appears to be implicated in excessive drinking, but heredity may also play a role. For example, the children of alcoholics are more likely than others to become alcoholics themselves; and if the children are identical twins, both are at increased risk for alcoholism, even when raised apart (Kendler et al., 1992; McGue, 1999; Slutske et al., 1998). The role of genetics appears to be greatest among people who begin their alcoholic drinking pattern at an early age and display other conduct problems as teenagers (McGue, Pickens, & Svikis, 1992; Slutske et al., 1998). It is still unclear just what might be inherited or which genes are involved. One possibility involves inherited abnormalities in the brain's neurotransmitter systems or in the body's metabolism of alcohol (Devor, 1994; Kranzler & Anton, 1994; Nurnberger et al., 2001). Males who are alcoholics do tend to be less sensitive than other males to the effects of alcohol—a factor that may contribute to greater consumption (Pollack, 1992; Schuckit, 1998). The recently completed decoding of the human genome is guiding researchers to focus on a few specific chromosomes as the possible location of genes that predispose people to—or protect them from—the development of alcoholism (Foroud et al., 2000; NIAAA, 2000; Reich et al., 1998).

Heroin and Cocaine Dependence Like alcoholics, heroin and cocaine addicts suffer many serious physical problems, both as a result of the drugs themselves and of the poor eating and other unhealthy habits that drug use engenders. The risk of death from an overdose, contaminated drugs, or AIDS (contracted through blood in shared needles), as well as from suicide, is also always present. Dependence on these drugs tends to be more prevalent among males, especially young males (Warner et al., 1995).

Continued use or overdoses of cocaine can cause problems ranging from nausea and hyperactivity to paranoid thinking, sudden depressive “crashes,” and even death. An estimated 1.5 million Americans have become physiologically dependent on cocaine, and millions more use it on occasion (National Institute on Drug Abuse,

1999). The widespread availability of crack, a powerful and relatively cheap form of cocaine, has made it one of the most dangerous and addicting drugs in existence. Pregnant women who use cocaine are much more likely than nonusers to lose their babies through spontaneous abortion, placental detachment, early fetal death, or stillbirth.

Although addiction to substances like heroin and cocaine is largely understood to be a biological process brought about by the physiological effects of the drugs, explaining why people first use them is more complicated. Beyond the obvious and immediate pleasure that these drugs provide, the causes of initial drug abuse are less well established than the reasons for alcohol abuse. One line of theorizing suggests that there might be a genetic tendency toward behavioral dysregulation or compulsion that predisposes some people to abuse many kinds of drugs, including alcohol (Holden, 1991; Smith et al., 1992). A study supporting this possibility found a link between alcoholism in biological parents and drug abuse in adopted-away sons (Cadoret et al., 1995). The same study also found a link between antisocial personality traits in biological parents and antisocial acts—including drug abuse—in the sons they had put up for adoption.

A number of psychological factors have been proposed as initial causes of substance abuse. One theory suggests that drug taking begins as self-medication for stress reactions or for the symptoms of anxiety, depression, schizophrenia, and other disorders that are seen in more than half of all substance abusers (Blanchard, 2000; U.S. Surgeon General, 1999). Other possible psychological causes include imitation of drug-using peers, impulsivity, thrill seeking, and social maladjustment. Research has still not established why drugs become a problem for some people and not for others, but as with so many other disorders, it is likely that some biological predisposition sets the stage on which specific psychological processes and stressors play out their roles in specific social and cultural contexts.

Mental Illness and the Law

Cheryl was barely twenty when she married Glen, a graduate student in biology. They moved into a large apartment complex near the university and within three years had two sons. Cheryl's friends had always been impressed by the attention and affection she showered on her boys; she seemed to be the ideal mother. She and Glen had serious marital problems, however, and she felt trapped and unhappy. One day Glen came home to find that Cheryl had stabbed both children to death. At her murder trial, she was found not guilty by reason of insanity and was placed in a state mental institution.

This verdict reflects U.S. laws and rules that protect people with severe psychological disorders when they are accused of crimes (Cassel & Bernstein, 2001). Similar laws and rules are in effect in many other countries as well. The protection takes two forms.

First, under certain conditions, people designated as mentally ill may be protected from prosecution. If, at the time of their trial, individuals accused of a crime are unable to understand the proceedings and charges against them or to assist in their own defense, they are declared to be *mentally incompetent to stand trial*. In such cases, defendants are sent to a mental institution until they are judged to have become mentally competent. If still not competent after a court-specified period—two years, in most cases—a defendant may be ruled permanently ineligible for trial and either committed in civil court to a mental institution or released. Release is rare, however, because competency to stand trial requires only minimal mental abilities. If drugs can produce even temporary mental competence, the defendant will usually go to trial (Nietzel, 1999).

Assessment of Mental Competence

Andrea Yates admitted to drowning all five of her children, one by one, in the bathtub of her Houston home in 2001. She had twice tried to kill herself in previous years, and she was reportedly depressed at the time of the murders. Accordingly, she pleaded not guilty by reason of insanity, but the first legal step in deciding her fate was to confine her in a mental institution for assessment of her mental competency to stand trial. Following the testimony of the psychologists who examined her, she was found competent, and ultimately sentenced to life in prison.

Second, mentally ill defendants may be protected from punishment. In most U.S. states, they may be judged *not guilty by reason of insanity* if, at the time of the crime, mental illness prevented them from (1) understanding what they were doing, (2) knowing that what they were doing was wrong, or (3) resisting the impulse to do wrong. The first two of these criteria—understanding the nature or wrongfulness of an act—are “cognitive” criteria known as the M’Naughton rule. This rule stems from an 1843 case in England in which a man named Daniel M’Naughton, upon hearing “instructions from God,” tried to kill British prime minister Robert Peel; he was found not guilty by reason of insanity and put into a mental institution for life. The third criterion, which is based on a defendant’s emotional state during a crime, is known as the irresistible-impulse test. All three criteria are combined in a rule proposed by the American Law Institute (ALI) in 1962 and now followed in about half of the U.S. states: “A person is not responsible for criminal conduct if at the time of such conduct as a result of mental disease or defect he lacks substantial capacity either to appreciate the criminality (wrongfulness) of his conduct or to conform his conduct to the requirements of law” (ALI, 1962, p. 66).

In 1984, after John Hinckley, Jr., was found not guilty by reason of insanity under the ALI rule for his attempted assassination of President Ronald Reagan, the U.S. Congress passed the Insanity Defense Reform Act, which eliminated the irresistible-impulse criterion from the definition of insanity in federal cases. Such laws highlight the fact that *insanity* is a legal term, not a psychiatric diagnosis; it does not appear in *DSM-IV* (Cassel & Bernstein, 2001). The responsibility falls on judges and juries to weigh evidence and testimony and decide whether or not a defendant should be held responsible for criminal acts. Defendants who are judged not guilty by reason of insanity and who still display a psychological disorder are usually required to receive treatment, typically through commitment to a hospital, until judged to be cured or no longer dangerous.

Insanity rules have been faulted on several grounds. Some critics argue that everyone, even those who meet legal criteria for insanity, should be held responsible for their actions and punished for their crimes. Others point out significant problems in the implementation of insanity rules. For one thing, different experts often give conflicting, highly technical testimony about a defendant’s sanity at the time of a crime. (One expert said Cheryl was sane; another concluded she was insane.) Jurors are then left in the difficult position of deciding which expert to believe and what to make of the experts’ diagnostic judgments. Their task is complicated by the

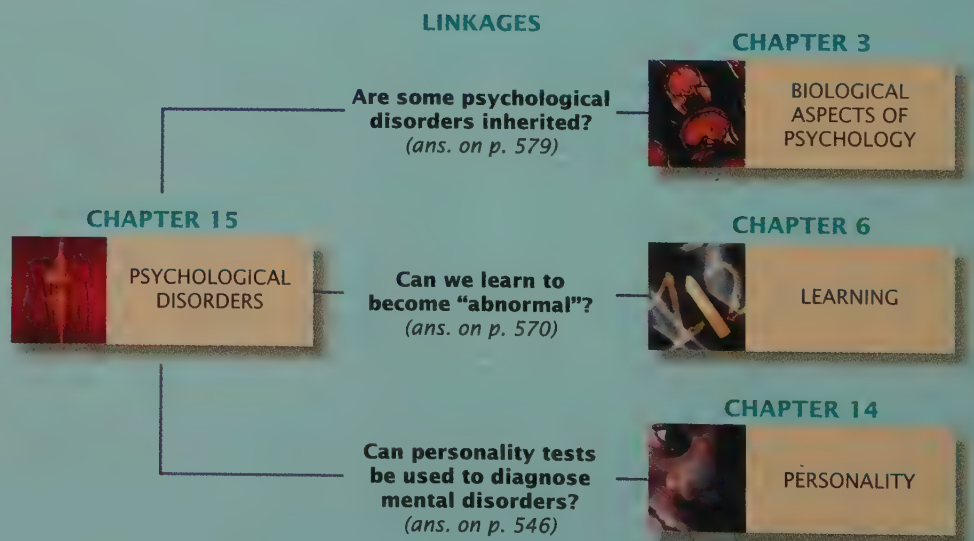

fact that people suffering from mental disorders—even those as severe as schizophrenia—are still capable of some rational decision making and of controlling some aspects of their behavior (Grisso & Applebaum, 1995). Concern over such problems has led two U.S. states, Idaho and Montana, to abolish the insanity defense. Other states have tried less extreme reforms. In twelve states, it is now possible for juries to find defendants *guilty but mentally ill*. These defendants still serve a sentence, and although they are supposed to receive treatment while confined, they seldom do (Cassel & Bernstein, 2001). A second reform already noted is that federal courts no longer use the irresistible-impulse criterion in defining insanity. Third, federal courts and some state courts now require defendants to prove that they were insane at the time of their crime, rather than requiring the prosecution to prove that the defendants were sane.

Does the insanity defense allow lots of criminals to “get away with murder”? No. Although certain high-profile cases might suggest otherwise, the insanity plea is used in fewer than 1 of every 200 felony cases in the United States—usually when the defendant displays severe psychological disorder—and this plea is successful in only 2 of every 1,000 attempts (Silver, Cirincione, & Steadman, 1994). Further, the few defendants found not guilty by reason of insanity are usually hospitalized for two to nine times as long as they would have spent in prison had they been convicted (Silver, 1995; Steadman, 1993). For example, John Hinckley, Jr., has been in St. Elizabeth’s hospital in Washington, D.C., since 1982, and in spite of his annual efforts to be released, he is unlikely to get out anytime soon.

In summary, legislators, victims’ rights groups, civil liberties advocates, and ordinary citizens are constantly seeking the proper balance between protecting the rights of defendants and protecting society from dangerous criminals. In doing so, the sociocultural values that shape views about what is abnormal also influence judgments about the extent to which abnormality should relieve people of responsibility for criminal behavior.

LINKAGES

As noted in the chapter on introducing psychology, all of psychology’s subfields are related to one another. Our discussion of how classical conditioning can lead to phobias illustrates just one way in which the topic of this chapter, psychological disorders, is linked to the subfield of learning (which is the focus of the chapter by that name). The Linkages diagram shows ties to two other subfields as well, and there are many more ties throughout the book. Looking for linkages among subfields will help you see how they all fit together and help you better appreciate the big picture that is psychology.

SUMMARY

Psychopathology involves patterns of thinking, feeling, and behaving that cause personal distress or that significantly impair a person's social or occupational functioning.

Defining Psychological Disorders

The definition of abnormality is largely determined by social and cultural factors.

What Is Abnormal?

The criteria for judging abnormality include statistical infrequency (a comparison with what most people do), norm violation, and personal suffering. Each of these criteria is flawed to some extent.

Behavior in Context: A Practical Approach

The practical approach to defining abnormality, which considers the content, context, and consequences of behavior, emphasizes the question of whether individuals show *impaired functioning* in fulfilling the roles appropriate for particular people in particular settings, cultures, and historical eras.

Explaining Psychological Disorders

Abnormal behavior has been attributed, at one time or another, to many different factors, including the action of supernatural forces.

The Biopsychosocial Model

In today's *biopsychosocial model*, mental disorders are attributed to the combination and interaction of biological, psychological, and sociocultural factors. Biological factors are emphasized by the medical, or *neurobiological model*, which sees psychological disorders as reflecting particular disturbances in the anatomy and chemistry of the brain and in other biological processes. The causal factors emphasized by the *psychological model* of mental disorders include unconscious conflicts, maladaptive cognitive schemas, learning, or blocked actualizing tendencies. The *sociocultural model* focuses on factors that help define abnormality and influence the form that disorders take in different parts of the world.

Diathesis-Stress as an Integrative Explanation

No single aspect of the biopsychosocial model can adequately explain all psychological disorders. However, the *diathesis-stress approach* takes all of them into account by suggesting that biological, psychological, and sociocultural characteristics create predispositions for disorder that are translated into symptoms in the face of sufficient amounts of stress.

Classifying Psychological Disorders

There seems to be a set of behavior patterns that roughly defines abnormality in most cultures.

A Classification System: DSM-IV

The dominant system for classifying abnormal behavior in North America is the *Diagnostic and Statistical Manual of Mental Disorders (DSM-IV)* of the American Psychiatric Association. It includes more than three hundred specific categories of mental disorders.

Purposes and Problems of Diagnosis

Diagnosis helps to identify the features, causes, and most effective methods of treating various psychological disorders. Research on the reliability and validity of *DSM-IV* shows that it is a useful, but imperfect, classification system.

Anxiety Disorders

Long-standing and disruptive patterns of anxiety characterize *anxiety disorders*.

Types of Anxiety Disorders

The most prevalent type of anxiety disorder is *phobia*, which includes *specific phobias*, *social phobias*, and *agoraphobia*. Other anxiety disorders are *generalized anxiety disorder*, which involves nonspecific anxiety; *panic disorder*, which brings unpredictable attacks of intense anxiety; and *obsessive-compulsive disorder (OCD)*, in which uncontrollable repetitive thoughts and ritualistic actions occur.

Causes of Anxiety Disorders

The most influential explanations of anxiety disorders suggest that they may develop through the combination of a biological predisposition for strong anxiety reactions and the impact of fear-enhancing thought patterns and learned anxiety responses.

Somatoform Disorders

Somatoform disorders, including *conversion disorder*, involve physical problems that have no apparent physical cause. Other examples are *hypochondriasis*, an unjustified concern over becoming ill; *somatization disorder*, in which the person complains of numerous, unconfirmed physical complaints; and *pain disorder*, in which pain is felt in the absence of a known physical cause.

Dissociative Disorders

Dissociative disorders involve rare conditions such as *dissociative fugue*, *dissociative amnesia*, and *dissociative identity disorder*, or *DID* (multiple personality disorder), in which a person suffers memory loss or develops two or more identities.

Mood Disorders

Mood disorders, also known as affective disorders, involve extreme moods that may be inconsistent with events.

Depressive Disorders

Major depressive disorder is marked by feelings of inadequacy, worthlessness, and guilt; in extreme cases, *delusions* may also occur. Also seen is *dysthymic disorder*, which includes similar but less severe symptoms persisting for a long period. Suicide is often related to these disorders.

Bipolar Disorders

Alternating periods of depression and *mania* characterize *bipolar I disorder*, which is also known as manic depression. *Cyclothymic disorder*, an alternating pattern of less extreme mood swings, is more common.

Causes of Mood Disorders

Mood disorders have been attributed to biological causes such as genetics—which underlie disruptions in neurotransmitter and endocrine systems—and irregularities in biological rhythms. Both loss of significant sources of reward and maladaptive patterns of thinking are among the psychological causes proposed. A predisposition toward some of these disorders may be inherited, although their appearance may be determined by a diathesis-stress process.

Schizophrenia

Schizophrenia is perhaps the most severe and puzzling disorder of all.

Symptoms of Schizophrenia

Among the symptoms of schizophrenia are problems in thinking, perception (often including *hallucinations*), attention, emotion, movement, motivation, and daily functioning.

Categorizing Schizophrenia

Although *DSM-IV* lists five major subtypes of schizophrenia (paranoid, disorganized, catatonic, undifferentiated, and residual), many researchers today favor a descriptive system that focuses on whether patients display mainly *positive symptoms* (such as hallucinations and disorganized thoughts) or *negative symptoms* (such as lack of speech and restricted emotional expression). Each category of symptoms may be traceable to different causes; predominantly negative symptoms tend to be associated with more severe disorder and less successful treatment outcomes.

Causes of Schizophrenia

Genetic factors, neurotransmitter problems, abnormalities in brain structure and functioning, and neurodevelopmental abnormalities are biological factors implicated in schizophrenia.

Psychological explanations have pointed to maladaptive learning experiences and disturbed family interactions. The diathesis-stress approach, often described in terms of the vulnerability model, remains a promising framework for research into the multiple causes of schizophrenia.

Personality Disorders

Personality disorders are long-term patterns of maladaptive behavior that may be disturbing to the person displaying them and/or to others. Examples include schizotypal, avoidant, narcissistic, and *antisocial personality disorders*.

A Sampling of Other Psychological Disorders

Psychological Disorders of Childhood

Childhood disorders can be categorized as externalizing disorders (such as conduct disorders or attention deficit hyperactivity disorder) and internalizing disorders (in which children show overcontrol and experience distress, as in separation anxiety disorder). Pervasive developmental disorders do not fall into either category and include the autistic spectrum disorders. In autistic disorder, which can be the most severe of these, children show no interest in, or attachment to, others.

Substance-Related Disorders

Substance-related disorders involving alcohol and other drugs affect millions of people. *Addiction* to, psychological dependence on, or abuse of these substances contributes to disastrous personal and social problems, including physical illnesses, accidents, and crime. Genetic factors may create a predisposition for *alcoholism*, but learning, cultural traditions, and other psychosocial processes are also important. In the case of dependence on heroin and cocaine, stress reduction, self-medication for other mental disorders, imitation, thrill seeking, and social maladjustment have been proposed as important causal factors, along with genetics. The exact causes of initial use of these drugs, however, are unknown.

Mental Illness and the Law

Current rules protect people accused of crimes from prosecution or punishment if they are mentally incompetent at the time of their trials or if they were legally insane at the time of their crimes. Difficulty in establishing the mental state of defendants and other knotty problems have created dissatisfaction with those rules and prompted a number of reforms, including the “guilty but mentally ill” verdict.

Community Psychology: From Treatment to Prevention

Linkages Summary

In the chapter on psychological disorders, we described José, a fifty-five-year-old electronics technician who had to take medical leave from his job after experiencing panic attacks (see Table 15.1). After four months of diagnostic testing turned up no physical problems, José's physician suggested that he see a psychologist. José resisted at first, insisting that his condition was not "just in his head," but he eventually began psychological treatment. Within a few months, his panic attacks had ceased, and José had returned to all his old activities. After the psychologist helped him reconsider his workload, José decided to retire from his job in order to pursue more satisfying work at his home-based computer business.

José's case is by no means unique. During any given year in the United States alone, about 15 percent of adults and about 21 percent of children are receiving some form of treatment for a psychological disorder (U.S. Surgeon General, 1999). Although the economic impact of mental disorders—in treatment costs, disability payments, and lost productivity—is a staggering \$150 billion per year in the United States, the treatments that are available today for severe disorders can pay for themselves. In fact, the savings realized from treatment are actually greater than its costs (Clay, 2000; National Institute of Mental Health, 1998). In this chapter, we describe a variety of treatment methods, most of which are based on the theories of stress and coping, personality, and psychological disorders reviewed in the chapters on those topics. By spelling out proposed explanations for what can go wrong in the development of personality and behavior and the role of stress in both, those theories provide important guidelines for treatment.

First we examine the basic features common to all forms of treatment. Then we discuss approaches that rely on **psychotherapy**, the treatment of psychological disorders through psychological methods, such as talking about problems and exploring new ways of thinking and acting. These methods are based on psychodynamic, humanistic, or social-cognitive (behavioral) theories of disorder and treatment. We then consider biological approaches to treatment, which consist mainly of drugs and other physical therapies.

Although we discuss different psychotherapy methods in separate sections, keep in mind that the majority of mental health professionals see themselves as *eclectic* therapists; in other words, they might lean toward one set of methods, but when working with particular clients or particular problems, they employ other methods as well (Hayes & Harris, 2000; Jensen, Bergin, & Greaves, 1990; Northcut & Heller, 1999). Further, many clients receive psychoactive drugs in addition to psychotherapy during the course of psychological treatment (Sammons & Schmidt, 2001).

Basic Features of Treatment

All treatments for psychological, as well as physical, disorders share certain basic features. These common features include a *client* or patient, a *therapist* who is accepted as being capable of helping the client, and the establishment of a *special relationship* between the client and therapist. In addition, all forms of treatment are based on some *theory* about the causes of the client's problems. The theory may presume causes ranging from magic spells to infections and everything in between (Frank & Frank, 1991). The theory, in turn, leads to *procedures* for dealing with the client's problems. So traditional healers combat supernatural forces with ceremonies and prayers, medical doctors treat chemical imbalances with drugs, and psychologists focus on altering psychological processes through psychotherapy.

People receiving treatment for psychological disorders can be inpatients or outpatients. *Inpatients* are treated in a hospital or other residential institution. They are voluntarily or involuntarily committed to these institutions because their impairments are severe enough to constitute a threat to their own well-being or the safety of others. Depending on their level of functioning, inpatients may stay in the hospital for a few days or weeks or—in rare cases—several years. Their treatment almost

psychotherapy The treatment of psychological disorders through talking and other psychological methods.

psychiatrists Medical doctors who have completed special training in the treatment of psychological disorders.

psychologists Therapists whose education includes completion of a master's or (usually) a doctoral degree in clinical or counseling psychology, often followed by additional specialty training.

Medieval Treatment Methods Methods used to treat psychological disorders have always been related to the presumed causes of those disorders. In medieval times, when demons were widely blamed for abnormal behavior, physician-priests tried to make the victim's body inhospitable to evil spirits. Here, we see a depiction of such spirits leaving an afflicted person's head as it is placed in an oven.

always includes psychoactive drugs. *Outpatients* receive psychotherapy and/or drugs while living in the community. Compared with inpatients, outpatients tend to be younger, are more likely to be female, and typically come from the middle or upper socioeconomic classes.

Those who provide psychological treatment are a diverse group. **Psychiatrists** are medical doctors who have completed specialty training in the treatment of psychological disorders. Like other physicians, they are authorized to prescribe drugs for the relief of psychological problems. **Psychologists** who offer psychotherapy have usually completed a doctoral degree in clinical or counseling psychology, often

Group Therapy for Vietnam Veterans

Some psychotherapy occurs in one-to-one office sessions, but treatment might also be conducted with couples, families, and groups in hospitals, community health centers, and facilities for former mental hospital residents. Therapy is also provided at prisons, military bases, drug and alcoholism treatment centers, and many other places.

followed by additional specialized training. Except in New Mexico, psychologists are not authorized to prescribe drugs, although there is debate over proposals to extend prescription privileges to clinical psychologists elsewhere who have been specially trained for this function (Ax & Resnick, 2001; Kilby, 1999; Newman et al., 2000). Other therapy providers include *clinical social workers*, *marriage and family therapists*, and *licensed professional counselors*, all of whom typically hold a master's degree in their respective professions and provide treatment in a variety of settings, such as hospitals, clinics, and private practice. *Psychiatric nurses*, *substance abuse counselors*, members of the clergy working as *pastoral counselors*, and a host of paraprofessionals also provide therapy services, often as part of a hospital or outpatient treatment team (U.S. Surgeon General, 1999).

The general goal of treatment providers is to help troubled people change their thinking, feelings, and behavior in ways that relieve discomfort, promote happiness, and improve their overall functioning as parents, students, workers, and the like. To reach this goal, some therapists try to help clients gain insight into the hidden causes of problems, others seek to promote growth through more genuine self-expression, and still others help clients learn and practice new ways of thinking and acting. The particular methods used in each case—whether some form of psychotherapy, a drug treatment, or both—depend on the problems, preferences, and financial circumstances of the client; the time available for treatment; and the therapist's theoretical leanings, methodological preferences, and professional qualifications. Later, we will discuss drugs and other biological treatments; here, we consider several forms of psychotherapy, each of which is based on psychodynamic, humanistic, or behavioral explanations of mental disorder.

Psychodynamic Psychotherapy

The field of formal psychotherapy began in the late 1800s when, as described in the chapter on personality, Sigmund Freud established the psychodynamic approach to psychological disorders. Central to his approach, and to modern revisions of it, is the assumption that personality and behavior reflect the efforts of the ego to referee conflicts, usually unconscious, among various components of the personality.

Freud's method of treatment, **psychoanalysis**, was aimed at understanding these unconscious conflicts and how they affect the client. His one-to-one method of studying and treating people, his search for relationships between an individual's life history and current problems, his emphasis on thoughts and emotions in treatment, and his focus on the client-therapist relationship have influenced almost all forms of psychotherapy. We describe Freud's original methods first, and then consider some more-recently developed treatments that are rooted in his psychodynamic approach.

Classical Psychoanalysis

Classical psychoanalysis developed mainly out of Freud's medical practice. He was puzzled by patients who suffered from "hysterical" ailments—blindness, paralysis, or other symptoms that had no apparent physical cause. (As mentioned in the chapter on psychological disorders, these ailments are now considered to be symptoms of *conversion disorders*.) Inspired by his colleague Josef Breuer's dramatic success in using hypnosis to treat hysterical symptoms in a patient known as "Anna O." (Breuer & Freud, 1895/1974), Freud tried similar methods with other hysteria patients but found them to be only partially and temporarily successful. Eventually, Freud merely asked patients to lie on a couch and report whatever thoughts, memories, or images came to mind (a process Freud called *free association*).

The results of this "talking cure" were surprising. Freud came to believe that his patients' problems stemmed from childhood memories of sexual abuse, usually by a parent or other close relative (Esterson, 2001). Freud wondered whether child abuse

psychoanalysis A method of psychotherapy that seeks to help clients gain insight by recognizing and understanding unconscious thoughts and emotions.

Freud's Consulting Room During psychoanalytic sessions, Freud's patients lay on this couch, free-associating or describing dreams and everyday events, while he sat in the chair behind them. According to Freud, even apparently trivial or accidental behavior may hold important messages from the unconscious. Forgetting a dream or missing a therapy appointment might reflect a client's unconscious resistance to treatment. Even accidents may be meaningful. The waiter who spills hot soup on an elderly male customer might be seen as acting out unconscious aggressive impulses against a father figure.

was rampant in Vienna, whether he was getting a biased sample of patients, or whether the memories he believed he had found were being distorted by psychological factors. He ultimately concluded that his patients' memories of childhood abuse probably reflected childhood fantasies, not reality—a conclusion that, as described in the chapter on personality, has become quite controversial. In any case, Freud focused psychoanalysis on the exploration of unconscious impulses and fantasies. Hysterical symptoms, he said, developed out of conflicts about those impulses and fantasies.

Classical psychoanalytic treatment aims to help clients gain insight into their problems by recognizing unconscious thoughts and emotions, and then discover, or *work through*, the many ways in which those unconscious elements affect their everyday lives. The treatment may require as many as three to five sessions per week, usually over several years. Generally, the psychoanalyst tries to maintain a compassionate neutrality during treatment as the client slowly develops an understanding of how past conflicts determine current problems (Auld & Hyman, 1991).

To gain glimpses into the unconscious, Freud looked for unconscious meaning in his patients' free associations, their dreams, their everyday behaviors, and their relationship with him. He believed that hidden beneath the obvious or *manifest content* of dreams, there is *latent content* that reflects the wishes, impulses, and fantasies that the dreamer's defense mechanisms keep out of consciousness during waking hours. He focused also on "Freudian slips" of the tongue (such as saying *beast* instead of *best*) and other seemingly insignificant, but potentially meaningful, behaviors. Similarly, a patient's expression of tenderness, fear, dependency, hostility, or the like during therapy was viewed by Freud as part of an unconscious transference to the therapist of feelings and conflicts experienced in childhood in relation to parents and other significant people. Analysis of this *transference*, this "new edition" of the client's childhood conflicts and current problems, became another important psychoanalytic method; Freud believed that focusing on the transference allows clients to see how old conflicts haunt their lives and to resolve these conflicts (Arlow, 1995).

Contemporary Variations on Psychoanalysis

Although classical psychoanalysis is still practiced, it is not as prevalent as it was several decades ago (Horgan, 1996). The decline is due to many factors, including disenchantment with Freud's personality theory; the expense of classical

A Play Therapy Session Modern versions of psychoanalytic treatment include fantasy play and other techniques that make the approach more useful with children. A child's behavior and comments while playing with puppets representing family members, for example, are seen as a form of free association that the therapist hopes will reveal important unconscious material, such as fear of abandonment (Booth & Lindaman, 2000).

psychoanalysis (Moran, 2000); its limited usefulness with children; and the availability of many alternative forms of treatment, including variations on classical psychoanalysis.

Some of these variations were developed by the neo-Freudian theorists discussed in the chapter on personality. As noted there, those theorists tended to put less emphasis than Freud did on the past and on unconscious impulses stemming from the id. They also tended to stress the role of social relationships in clients' problems and how the power of the ego can be harnessed to solve those problems. *Ego analysis* (Hartmann, 1958; Klein, 1960), *interpersonal therapy* (Sullivan, 1954), and *individual analysis* (Adler, 1927/1963) were among the first treatments to be based on neo-Freudian theories; some were designed for treating children (A. Freud, 1946; Klein, 1960). More recent variants have come to be known as *short-term dynamic psychotherapy* because they aim to provide benefits in far less time than is required in classical psychoanalysis (Davanloo, 1999).

A particularly popular short-term dynamic approach is known as *object relations therapy* (Scharff & Scharff, 1998; St. Clair, 1999). (The term *object* refers to anything, including a person, that has had emotional significance in a client's life.) In object relations therapy, the powerful need for human contact and support takes center stage. In fact, object relations therapists believe that most of the problems that bring clients to treatment ultimately stem from this need and how it plays out in their relationships with others—especially with their mothers or other early caregivers. Psychotherapists who adopt an object relations perspective take a much more active role in therapy sessions than classical analysts do—particularly by directing the client's attention to evidence of certain conflicts, rather than waiting for free association or other more subtle methods to reveal these conflicts. Object relations therapists work to develop a nurturing relationship with their clients, providing a “second chance” for them to receive the support that might have been lacking in infancy and to counteract some of the consequences of maladaptive early attachment patterns (Lieberman & Pawl, 1988). One way they do this is to show that they will not abandon their clients, as might have happened to these people in the past.

Other variations on psychoanalysis retain more of Freud's ideas but alter the format of treatment so that it is less intense, less expensive, and more appropriate

Analysis of the transference would be quite a challenge in this parody of a psychoanalytic therapy relationship! Psychoanalysts focus not only on their clients' feelings toward them but also on their feelings toward clients—called *countertransference*. For example, if transference leads a client to treat the therapist as a mother, the therapist might, because of countertransference, unintentionally begin treating the client as her child.

*"What do you think I think about what you think
I think you've been thinking about?"*

for a broader range of clients (Hoyt, 1995). For example, *psychoanalytically oriented psychotherapy* and *time-limited dynamic psychotherapy* employ classical psychoanalytic methods but use them more flexibly (Levenson & Strupp, 1997). The goal of treatment may range from giving psychological support to achieving basic changes in personality, and therapy may be completed in fewer than thirty sessions. A therapist using these briefer psychodynamic methods encourages clients to focus on concrete, specific goals. For example, the therapist might ask a client to describe how he or she would feel and act if a specific problem were suddenly solved.

Some version of transference analysis is seen in virtually all variations on classical psychoanalysis. In a short-term psychodynamic treatment called *supportive-expressive therapy*, for example, the therapist looks for a "core conflict" that appears repeatedly across a variety of relationships, including in the therapy relationship (Luborsky, 1997; Luborsky & Crits-Christoph, 1998). The core conflict in one young man, for example, centered on his desire to stand up for himself and his tendency to criticize himself for having that desire. (As a child, the client had been physically abused by his father.) The therapist watched for this core conflict to appear in the therapy relationship—as when tentative assertiveness was tempered by fear of having done wrong—and then helped the client see the links among his fear of asserting himself, his fantasies of getting even, and his childhood abuse experiences. This interpretation is part of transference analysis (Luborsky, 1997). At the same time, the therapist supported the client's attempts to be more assertive with authority figures without having violent fantasies.

With their focus on interpersonal relationships rather than instincts, their emphasis on clients' potential for self-directed problem solving, and the reassurance and emotional support they provide, contemporary variants on classical psychoanalysis have helped the psychodynamic approach retain its influence among mental health professionals (Westen & Gabbard, 1999).

Humanistic Psychotherapy

As discussed in the chapters on personality and psychological disorders, *humanistic psychologists* emphasize the subjective interpretations that people place on events. Humanists (sometimes called *phenomenologists*) view people as capable of consciously controlling their own actions and taking responsibility for their own decisions. Humanistic therapists believe that human behavior is motivated not by sexual or aggressive impulses but rather by an innate drive toward growth that is guided from moment to moment by the way people perceive their world. Disordered behavior, they say, reflects a blockage of natural growth brought on by distorted perceptions or lack of awareness of feelings. Accordingly, humanistic (or phenomenological) therapy operates on the following assumptions:

1. Treatment is an encounter between equals, not a cure provided by an expert. It is a way to help clients restart their natural growth and to feel and behave more in line with that growth.
2. Clients will improve on their own, given the right conditions. These ideal conditions promote clients' awareness, acceptance, and expression of their feelings and perceptions. So, like psychodynamic therapy, humanistic therapy promotes insight, but it is insight into current feelings and perceptions, not into unconscious childhood conflicts.
3. Ideal conditions in therapy can best be established through a relationship in which clients feel fully accepted and supported as human beings, no matter how problematic or undesirable their *behavior* may be. It is the client's experience of this relationship that brings beneficial changes. (As noted earlier, this assumption is also important in object relations therapy.)
4. Clients must remain responsible for choosing how they will think and behave.

Of the many humanistically oriented treatments in use today, the most influential are client-centered therapy, developed by Carl Rogers, and Gestalt therapy, developed by Frederick and Laura Perls.

Client-Centered Therapy

Carl Rogers was trained in psychodynamic methods during the 1930s, but he soon began to question their value. He especially disliked being a detached expert observer whose task was to "figure out" the client. He became convinced that a less formal approach would be more effective for the client and more comfortable for the therapist. Accordingly, Rogers developed *nondirective therapy*, which depends on the client's own drive toward growth or actualization. Rogers allowed his clients to decide what to talk about and when, without direction, judgment, or interpretation by the therapist (Raskin & Rogers, 1995). This approach, now called **client-centered therapy** or **person-centered therapy**, relies on the creation of a relationship that reflects three intertwined attitudes of the therapist: unconditional positive regard, empathy, and congruence.

Unconditional Positive Regard

The attitude Rogers called **unconditional positive regard** consists of treating the client as a valued person, no matter what. It is communicated through the therapist's willingness to listen to what the client has to say, without interrupting or evaluating it. The therapist doesn't have to approve of everything the client says, but must accept each statement as reflecting a part of the person who said it. Because they trust clients to solve their own problems, Rogerian therapists rarely give advice. Doing so, said Rogers, would send clients an unspoken message that they are incompetent, making them less confident and more dependent on help.

client-centered therapy A therapy that allows the client to decide what to talk about, without direction, judgment, or interpretation from the therapist.

unconditional positive regard A therapist attitude that conveys a caring for, and acceptance of, the client as a valued person.

A Client-Centered Therapy Group

Carl Rogers (shown here in shirtsleeves) believed that as successful treatment progresses, clients become more self-confident, more aware of their feelings, more accepting of themselves, more comfortable and genuine with other people, more reliant on self-evaluation than on the judgments of others, and more effective and relaxed.

Empathy Client-centered therapists try to appreciate how the world looks from the client's point of view. This involves far more than saying "I know what you mean." The therapist tries to replace an *external frame of reference*—looking at the client from the outside—with an *internal frame of reference* characterized by **empathy**, the emotional understanding of what the client might be thinking and feeling. Client-centered therapists convey empathy by showing that they are *actively listening* to the client. Like other skillful interviewers, they make eye contact with the client, nod in recognition as the client speaks, and give other signs of careful attention. They also use **reflection**, a paraphrased summary of the client's words that emphasizes the feelings and meanings that appear to accompany them; reflection confirms the communication, shows that the therapist is interested, and helps the client to perceive and focus on the thoughts and feelings being expressed. Here is an example:

CLIENT: This has been such a bad day. I've felt ready to cry any minute, and I'm not even sure what's wrong!

THERAPIST: You really do feel so bad. The tears just seem to well up inside, and I wonder if it is a little scary to not even know why you feel this way.

Notice that in rephrasing the client's statements, the therapist reflected back not only the obvious feelings of sadness but also the fear in the client's voice. Most clients respond to empathic reflection by elaborating on their feelings. In this example, the client went on to say, "It is scary, because I don't like to feel in the dark about myself. I have always prided myself on being in control." Clients do this, said Rogers, simply because the therapist expresses the desire to listen and understand without asking disruptive questions. Empathic listening tends to be so effective in promoting self-understanding and awareness that it is used across a wide range of therapies (Corsini & Wedding, 2001). Even outside the realm of therapy, people who are thought of as easy to talk to are usually "good listeners" who reflect back the important messages they hear from others.

empathy The therapist's attempt to appreciate and understand how the world looks from the client's point of view.

reflection An active listening method in which a therapist conveys empathy by paraphrasing clients' statements and noting accompanying feelings.

congruence A consistency between the way therapists feel and the way they act toward clients.

Congruence Sometimes called *genuineness*, **congruence** refers to a consistency between the therapist's feelings and actions. When the therapist's unconditional

Nonverbal Cues in Gestalt Therapy

Gestalt therapists pay particular attention to clients' "body language," especially when it conflicts with what they are saying. If this client had just said that she was looking forward to starting her new job, the therapist would probably challenge that statement in an effort to make the client more aware of her mixed feelings.

positive regard and empathy are genuine, the client is able to see that relationships can be built on openness and honesty. Ideally, this experience will help the client become more congruent in other relationships.

Here is an excerpt that illustrates the three therapist attitudes we have described.

CLIENT: . . . *I cannot be the kind of person I want to be. I guess maybe I haven't the guts or the strength to kill myself, and if someone else would relieve me of the responsibility or I would be in an accident I, I . . . just don't want to live.*

THERAPIST: *At the present time things look so bad that you can't see much point in living. [Note the use of empathic reflection and the absence of any criticism.]*

CLIENT: *Yes. I wish I'd never started this therapy. I was happy when I was living in my dream world. There I could be the kind of person I wanted to be. But now there is such a wide, wide gap between my ideal and what I am. . . . [Notice that the client responds to reflection by giving more information.]*

THERAPIST: *It's really a tough struggle digging into this like you are, and at times the shelter of your dream world looks more attractive and comfortable. [Note the use of reflection.]*

CLIENT: *My dream world or suicide. . . . So I don't see why I should waste your time—coming in twice a week—I'm not worth it—what do you think?*

THERAPIST: *It's up to you. . . . It isn't wasting my time. I'd be glad to see you whenever you come but it's how you feel about it. . . . [Note the congruence in stating an honest desire to see the client and the unconditional positive regard in trusting her capacity and responsibility for choice.]*

CLIENT: *You're not going to suggest that I come in oftener? You're not alarmed and think I ought to come in every day until I get out of this?*

THERAPIST: *I believe you are able to make your own decision. I'll see you whenever you want to come. [Note the unconditional positive regard.]*

CLIENT: *(Note of awe in her voice) I don't believe you are alarmed about—I see—I may be afraid of myself but you aren't afraid for me. [Here the client experiences the therapist's confidence in her. Happily, she did not kill herself.] (Rogers, 1951, p. 49)*

Gestalt Therapy

Frederick S. (Fritz) Perls, a European psychoanalyst, was greatly influenced by research in *Gestalt psychology*. (As noted in the chapter on perception, Gestalt psychologists emphasized the idea that people actively organize their perceptions of the world.) Perls believed that (1) people create their own versions of reality and (2) people's natural psychological growth continues only as long as they perceive, remain aware of, and act on their true feelings. Growth stops and symptoms appear, said Perls, when people are not aware of all aspects of themselves (Perls, 1969; Perls, Hefferline, & Goodman, 1951).

Perls and his wife, Laura, developed Gestalt therapy on the basis of these beliefs. Like client-centered therapy, **Gestalt therapy** seeks to create conditions in which clients can become more unified, self-aware, and self-accepting—and thus ready to grow again. However, Gestalt therapists use more direct and dramatic methods than do Rogerians. Often working in group settings, Gestalt therapists prod clients to become aware of feelings and impulses that they have disowned and to discard feelings, ideas, and values that are not really their own. For example, the therapist or other group members might point out inconsistencies between what clients say and how they behave. Gestalt therapists may also ask clients to engage in imaginary

Gestalt therapy An active treatment designed to help clients get in touch with genuine feelings and disown foreign ones.

“conversations” with other people, with parts of their own personalities, and even with objects. Like a shy person who can be socially outgoing only while in a Halloween costume, clients often find that these dialogues help to get them in touch with, and to express, their feelings (Paivio & Greenberg, 1995).

Behavior Therapy

Psychodynamic and humanistic approaches to therapy assume that if clients gain insight or self-awareness about underlying problems, the symptoms created by those problems will disappear. Behavior therapists emphasize a different kind of insight or self-awareness: They encourage clients to think about psychological problems as *learned behaviors* that can be changed without first searching for hidden meanings or underlying processes (Miltenberger, 2001).

For example, suppose you have a panic attack every time you leave home and find relief only when you return. Making excuses when friends invite you out eases your anxiety temporarily but does nothing to solve the problem. Could you reduce your fear without looking for its “underlying meaning”? *Behavior therapy* would offer just such an alternative by first identifying the learning principles that maintain your fear and then helping you to develop new responses in feared situations.

These goals are based on both the *behavioral approach* to psychology and the *social-cognitive approach* to personality and disorder. As described in the chapters on introducing psychology, on personality, and on psychological disorders, these approaches emphasize the role of learning in the development of personality, as well as in most psychological disorders. Accordingly, behaviorists tend to see those disorders as examples of the maladaptive thoughts and actions that a client has learned. For instance, behavior therapists believe that fear of leaving home (agoraphobia) develops through classically conditioned associations between being away from home and having panic attacks. The problem is maintained in part through operant conditioning: Staying home and making excuses for doing so are rewarded by reduced anxiety. Therapists adopting a behavioral approach argue that if learning experiences can create problems, they can also help to alleviate those problems. So even if the experiences that led to today’s problems began in the client’s childhood, behavior therapy seeks to solve those problems by creating beneficial new experiences using the principles discussed in the chapter on learning.

Inspired by John B. Watson, Ivan P. Pavlov, B. F. Skinner, and others who studied learning during the 1920s and 1930s, researchers in the late 1950s and early 1960s began to systematically apply the principles of classical conditioning, operant conditioning, and observational learning to alter disordered human behavior (Thorpe & Olson, 1997). By 1970, behavioral treatment had become a popular alternative to psychodynamic and humanistic methods.

Some of the most notable features of behavioral treatment include the following:

1. Development of a productive therapist-client relationship. As in other therapies, this relationship enhances clients’ confidence that change is possible, makes it easier for them to be open about the nature and history of their problems, and increases their motivation to work toward improvement. In fact, behavior therapists see the therapeutic relationship as central to the success of treatment because it provides the context in which adaptive new learning can take place (Cahill, Carrigan, & Evans, 1998; Wilson, 1995).
2. A careful listing of the behaviors and thoughts to be changed. This assessment—and the establishment of specific goals—sometimes replaces the formal diagnosis used in some other therapy approaches. So instead of treating “depression” or “obsessive-compulsive disorder,” behavior therapists work to change the specific thoughts, behaviors, and emotional reactions that led to these diagnostic labels.

Virtual Desensitization A client who fears heights wears a virtual reality display that allows him to “experience” what he would see as a glass elevator gradually rises higher and higher. After learning to tolerate these realistic images without anxiety, clients are better able to fearlessly face the situations they once avoided.

behavior therapy Treatments that use classical conditioning principles to change behavior.

behavior modification Treatments that use operant conditioning methods to change behavior.

cognitive-behavior therapy Learning-based treatment methods that help clients change the way they think, as well as the way they behave.

systematic desensitization A behavioral treatment for anxiety in which clients visualize a graduated series of anxiety-provoking stimuli while remaining relaxed.

modeling Demonstrating desirable behaviors as a way of teaching them to clients.

assertiveness and social skills training A method for teaching clients how to interact with others more comfortably and effectively.

positive reinforcement A therapy method that uses rewards to strengthen desirable behaviors.

3. A therapist who acts as a kind of teacher/assistant by providing learning-based treatments, giving “homework” assignments, and helping the client make specific plans for dealing with problems.
4. Continuous monitoring and evaluation of treatment, along with constant adjustments to any procedures that do not seem to be effective.

Behavioral treatment can take many forms. By tradition, those methods that rely mainly on *classical conditioning* principles are usually referred to as **behavior therapy**. Methods that focus on *operant conditioning* principles are usually called **behavior modification**. And behavioral treatment that focuses on changing thinking patterns as well as overt behaviors is called **cognitive-behavior therapy**.

Techniques for Modifying Behavior

Some of the most important and commonly used behavioral treatment techniques are systematic desensitization, modeling, positive reinforcement, extinction, aversive conditioning, and punishment.

Systematic Desensitization Joseph Wolpe (1958) developed one of the first behavioral methods for helping clients overcome phobias and other forms of anxiety. Called **systematic desensitization**, it is a method in which the client visualizes a series of anxiety-provoking stimuli while remaining relaxed. Wolpe believed that this process gradually weakens the learned association between anxiety and the feared object, until the fear disappears.

Wolpe first arranged for clients to do something that is incompatible with being afraid. He often used *progressive relaxation training* (described in the chapter on health, stress, and coping) to prevent anxiety. Then, while relaxing, the client would be asked to imagine an item from a *desensitization hierarchy*, a sequence of increasingly fear provoking situations (see Table 16.1). The client would imagine one hierarchy item at a time, moving to a more difficult scene only after tolerating the previous one without distress. Wolpe found that once clients could calmly imagine being in feared situations, they were better able to deal with them in reality later on.

Desensitization appears especially effective if it slowly and carefully presents clients with real, rather than imagined, hierarchy items (Chambless, 1990; McGlynn et al., 1999). This *in vivo*, or “real life,” desensitization was once difficult to arrange or control, especially in cases involving fear of flying, heights, or highway driving, for example. Recently, however, a technique known as *virtual reality graded exposure* is making it possible for clients to “experience” extremely vivid and precisely graduated versions of feared situations without actually being exposed to them. In one study, clients who feared heights wore a head-mounted virtual reality helmet that gave them the impression of standing on bridges of gradually increasing heights, on outdoor balconies at higher and higher floors, and in a glass elevator as it slowly rose forty-nine stories (Rothbaum et al., 1995). The same technology has been used successfully in the treatment of many other anxiety disorders, ranging from fear of spiders or air travel to posttraumatic stress disorder (Klein, 1999; Robbins, 2000; Rothbaum & Hodges, 1999; Rothbaum et al., 1999, 2000).

Exactly why systematic desensitization works is not clear. Traditionally, clinicians believed that change occurs because of basic learning processes—either through classical conditioning of a new, calmer response to the fear-provoking stimulus or through extinction, as the object or situation that had been a conditioned fear stimulus repeatedly occurs without being paired with pain or any other unconditioned stimulus (Rachman, 1990). More recent explanations emphasize that desensitization also modifies clients’ cognitive processes, including their expectation that they can deal calmly and successfully with previously feared situations (Kehoe & Macrae, 1998).

Desensitization hierarchies are lists of increasingly fear provoking situations that clients visualize while using relaxation methods to remain calm. Here are a few items from the beginning and the end of a hierarchy that was used to help a client overcome fear of flying.

table 16.1 A Desensitization Hierarchy

1. You are reading a newspaper and notice an ad for an airline.
2. You are watching a television program that shows a group of people boarding a plane.
3. Your boss tells you that you need to take a business trip by air.
4. You are in your bedroom packing your suitcase for your trip.
- .
- .
- .
12. Your plane begins to move as you hear the flight attendant say, "Be sure your seat belt is securely fastened."
13. You look at the runway as the plane is readied for takeoff.
14. You look out the window as the plane rolls down the runway.
15. You look out the window as the plane leaves the ground.

figure 16.1

Participant Modeling in the Treatment of Snake Phobia

In this study, participant modeling was compared with systematic desensitization, symbolic modeling (watching filmed models), and no treatment (control). Notice that compared with no treatment, all three methods helped snake-phobic clients approach live snakes, but participant modeling was clearly the best; 92 percent of the participants in that group were virtually free of any fear. The value of participant modeling has been repeatedly confirmed (e.g., Öst, Salkovskis, & Hellström, 1991).

Modeling Therapists often teach clients desirable behaviors by demonstrating those behaviors. In **modeling** treatments, the client watches the therapist or other people perform desired behaviors, thus learning skills vicariously, or at second hand, without going through a lengthy shaping process. In fear treatment, for example, modeling can teach the client how to respond fearlessly while vicariously extinguishing conditioned fear responses. For example, one therapist showed a twenty-four-year-old student with a severe spider phobia how to kill spiders with a fly swatter and had her practice this skill at home with rubber spiders (MacDonald & Bernstein, 1974). The combination of live modeling with gradual practice is called *participant modeling*; it is one of the most powerful treatments for fear (Bandura, Blanchard, & Ritter, 1969; Faust, Olson, & Rodriguez, 1991; see Figure 16.1).

Modeling is also a major part of **assertiveness training** and **social skills training**, which teach clients how to interact with people more comfortably and effectively. The goals of social skills training range from helping social-phobic singles make conversation on dates to rebuilding the abilities of mental patients to interact normally with people outside the hospital (Fairweather & Fergus, 1993; Trower, 1995; Wong et al., 1993). In assertiveness training, the therapist helps clients learn to be more direct and expressive in social situations. *Assertiveness* does not mean aggressiveness; it means clearly and directly expressing both positive and negative feelings and standing up for one's rights while respecting the rights of others (Alberti & Emmons, 1986; Ballou, 1995). Assertiveness training is often conducted in groups and involves both modeling and role playing of specific situations. For example, group assertiveness training has helped wheelchair-bound adults more comfortably handle the socially awkward situations in which they sometimes find themselves (Gleuckauf & Quittner, 1992; Weston & Went, 1999).

Positive Reinforcement Behavior therapists also use systematic **positive reinforcement** to alter problematic behaviors and to teach new skills in cases ranging from childhood tantrums and juvenile delinquency to schizophrenia and self-starvation. Using operant conditioning principles, they set up *contingencies*, or rules, that specify the behaviors to be strengthened through reinforcement. In one study, autistic children, who typically use very little language, were given grapes, popcorn, or other items they liked in return for saying "please," "thank you," and "you're welcome" while exchanging crayons and blocks with a therapist. The therapist first modeled the behavior by saying the appropriate words. The children

figure 16.2

Positive Reinforcement for an Autistic Child

During each pretreatment baseline period, the child rarely said “please,” “thank you,” or “you’re welcome,” but these statements began to occur once they were modeled and then reinforced. Did modeling and reinforcement actually cause the change? They probably did, because each type of response did not start to increase until the therapist began demonstrating it.

almost immediately began to utter the phrases spontaneously. The effects generalized to situations involving other toys, and as indicated in Figure 16.2, the new skills were still evident six months later (Matson et al., 1990).

For severely retarded or disturbed clients in institutions, behavior therapists sometimes establish a **token economy**, a system for reinforcing desirable behaviors with coin-like tokens or points that can be exchanged later for snacks, access to television, or other desired rewards (Ayllon, 1999; Ayllon & Azrin, 1968; Paul & Lentz, 1977). The goal is to shape behavior patterns that will persist outside the institution (Paul, 2000; Paul, Stuve, & Cross, 1997).

Extinction Just as reinforcement can make desirable behaviors more likely, other behavioral techniques can make undesirable behaviors less likely. In operant conditioning, **extinction** is the process of removing the reinforcers that normally follow a particular response. If you have ever given up telephoning someone whose line has been busy for hours, you know how extinction works: When a behavior does not “pay off,” people usually stop it. Extinction changes behavior rather slowly, but it has been a popular way of treating children and retarded or seriously disturbed adults because it provides a gentle way to eliminate undesirable behaviors. For example, a client who gets attention by disrupting a classroom, damaging property, or violating hospital rules might be placed in a quiet, boring “time out” room for a few minutes in order to interrupt reinforcement for this misbehavior (e.g., Kee, Hill, & Weist, 1999; Reitman & Drabman, 1999).

Extinction is also the basis of a fear-reduction treatment called **flooding**, a procedure that keeps people in a feared but harmless situation, depriving them of their normally rewarding escape pattern (Barlow, 1988). (Flooding and related methods based on the extinction of classically conditioned fear responses are also called *exposure techniques*.) When someone is kept in contact with a fear-eliciting conditioned stimulus (a frog, say) without experiencing pain, injury, or any other aversive unconditioned stimulus, the fear-provoking power of the conditioned stimulus eventually fades, and the conditioned fear response extinguishes (Harris & Goetsch,

token economy A system for improving the behavior of institutionalized clients in which desirable behaviors are rewarded with tokens that can be exchanged for desired items or activities.

extinction The gradual disappearance of a conditioned response or operant behavior through nonreinforcement.

flooding A procedure for reducing anxiety that involves keeping a person in a feared, but harmless, situation.

Treating Fear Through Flooding

Flooding is designed to extinguish anxiety by allowing it to occur without the harmful consequences the person dreads. This man's fear of flying is obvious here, on takeoff, but is likely to diminish during and after uneventful flight. Like other behavioral treatments, flooding is based on the idea that phobias and other psychological disorders are learned and thus can be "unlearned."

1990; Öst et al., 2001). In one study, twenty clients who feared needles were exposed for two hours to the sight and feel of needles, including mild finger pricks, harmless injections, and blood samplings (Öst, Hellström, & Kåver, 1992). Afterward all the clients except one were able to have a blood sample drawn without experiencing significant anxiety.

Although often highly effective, flooding is equivalent to immediately exposing a fearful client to the most distressing item on a desensitization hierarchy. Therefore, some therapists and clients prefer more gradual exposure methods, especially in cases of agoraphobia and other problems in which a client's fear is not focused on a specific stimulus (Hecker & Thorpe, 1992). In dealing with agoraphobia, for instance, the therapist might provide gradual exposure by escorting the client away from home for increasing periods and eventually venturing into shopping malls and other previously avoided places (Kleinknecht, 1991; Zuercher-White, 1997). Clients can also practice gradual exposure methods on their own. They might be instructed, for example, to spend a little more time each day looking at photos of some feared animal or to spend some time alone in a dental chair or waiting room. In one study, clients suffering from various phobias made as much progress after six hours of instruction in gradual self-exposure methods and daily "homework" exercises as did those who received an additional nine hours of therapist-aided gradual exposure (Al-Kubaisy et al., 1992). Effective self-treatment using gradual exposure has also been reported in cases of panic disorder (Hecker et al., 1996) and obsessive-compulsive disorder (Fritzler, Hecker, & Losee, 1997).

Aversive Conditioning

Some unwanted behaviors—such as eating junk food or engaging in certain sexual offenses—can become so habitual and temporarily rewarding that they must be made less attractive if the client is to have any chance of giving them up in favor of a more desirable alternative. Methods for reducing the appeal of certain stimuli are known as **aversive conditioning** because they use classical conditioning principles to associate physical or psychological discomfort with behaviors, thoughts, or situations the client wants to stop or avoid (e.g., Clapham & Abramson, 1985).

One form of aversive conditioning, called *covert sensitization*, operates in a way that is the reverse of systematic desensitization. The client first visualizes the stimulus or situation that is to be made less attractive and is then exposed to frightening or disgusting stimuli. In one case, covert sensitization was used to treat a man who had been repeatedly arrested for making obscene phone calls. While imagining making an obscene call, the client heard vivid descriptions of his greatest fears: snakes, vomiting, and choking. Finally, he was told to imagine his mother walking in on him during a call. After a month of treatment, the thought of making obscene calls was no longer sexually arousing, and even two years later, the client had still not made any (Moergen, Merkel, & Brown, 1990).

Because aversive conditioning is unpleasant and uncomfortable and its effects are often temporary, behavior therapists use this method relatively rarely, only when it is the best treatment choice, and only long enough to allow the client to learn more desirable alternative behaviors.

Punishment

Sometimes the only way to eliminate a dangerous or disruptive behavior is to punish it with an unpleasant but harmless stimulus, such as a shouted "No!" or a mild electrical shock. Unlike aversive conditioning, in which the unpleasant stimulus occurs along with the behavior that is to be eliminated (a classical conditioning approach), **punishment** is an operant conditioning technique; it presents the unpleasant stimulus *after* the undesirable response occurs. (Although technically distinct, the two methods may overlap.) Before behavior therapists use mild shock or any other form of punishment with the institutionalized clients, other impaired adults, or children for whom it might be appropriate and beneficial, they must consider certain ethical questions. Among these are the following: Would the

aversive conditioning A method that uses classical conditioning to create a negative response to a particular stimulus.

punishment A therapy method that weakens undesirable behavior by following it with an unpleasant stimulus.

Albert Ellis Rational-emotive behavior therapy (REBT) focuses on altering the self-defeating thoughts that Ellis believes underlie people's behavior disorders. Ellis argues, for example, that students do not get upset because they fail a test but because they have learned to believe that failure is a disaster that indicates they are worthless. Many of Ellis's ideas have been incorporated into various forms of cognitive-behavior therapy, and they helped Ellis himself to deal rationally with the health problems he encountered when he reached his eighties (Ellis, 1997).

rational-emotive behavior therapy (REBT) A treatment designed to identify and change self-defeating thoughts that lead to anxiety and other symptoms of disorder.

cognitive therapy A treatment in which the therapist helps clients to notice and change negative thoughts associated with anxiety and depression.

client's life be in danger without treatment? Have all other methods failed? Has an ethics committee reviewed and approved the procedures? And has the client or a close relative formally agreed to the treatment? (Kazdin, 1994a). When the answer to these questions is yes, punishment can be an effective, sometimes lifesaving, treatment—as in the case illustrated in Figure 6.11 in the chapter on learning. Like extinction and aversive conditioning, punishment is best used only long enough to eliminate undesirable behavior and in combination with other behavioral methods designed to reward more appropriate behavior.

Cognitive-Behavior Therapy

Like psychodynamic and phenomenological therapists, behavior therapists recognize that depression, anxiety, and many other behavior disorders can stem from how clients think about themselves and the world. And like other therapists, behavior therapists also try to change their clients' troublesome ways of thinking. However, the methods used by behavior therapists—known collectively as *cognitive-behavior therapy*—rely on learning principles to help clients change the way they think (Goldfried et al., 1997; McMullin, 2000; Sperry, 1999). Suppose, for example, that a client suffers intense anxiety in social situations, in spite of having excellent social skills. In that case, social skills training would be unnecessary. Instead, the behavior therapist might combine relaxation training with cognitive-behavioral methods designed to help the client identify the habitual thoughts (such as “I shouldn’t draw attention to myself”) that get in the way of self-expression and create discomfort. Once these cognitive obstacles are brought to light, the therapist would encourage the client to develop more adaptive ways of thinking, as well as new ways of behaving in accordance with those new thoughts (Meichenbaum, 1995).

Rational-Emotive Behavior Therapy One prominent form of cognitive-behavior therapy is **rational-emotive behavior therapy (REBT)**. Developed by Albert Ellis (1962, 1993, 1995), and originally called *rational-emotive therapy*, rational-emotive behavior therapy is based on the principle that anxiety, guilt, depression, and other psychological problems are caused by how people think about events. Ellis's therapy aims first at identifying self-defeating thoughts such as “I must be loved or approved by everyone” or “I must be perfectly competent, adequate, and achieving to be worthwhile.” After the client learns to recognize thoughts like these and to see how they cause problems, the therapist uses modeling, encouragement, and logic to help the client replace these thoughts with more realistic and beneficial ones. Here is part of a rational-emotive behavior therapy session with a thirty-nine-year-old woman who suffered from panic attacks. She has just said that it would be “terrible” if she had an attack in a restaurant and that people “should be able to handle themselves!”

THERAPIST: . . . *The reality is that . . . “shoulds” and “musts” are the rules that other people hand down to us, and we grow up accepting them as if they are the absolute truth, which they most assuredly aren’t.*

CLIENT: *You mean it is perfectly okay to, you know, pass out in a restaurant?*

THERAPIST: *Sure!*

CLIENT: *But . . . I know I wouldn’t like it to happen.*

THERAPIST: *I can certainly understand that. It would be unpleasant, awkward, inconvenient. But it is illogical to think that it would be terrible, or . . . that it somehow bears on your worth as a person.*

CLIENT: *What do you mean?*

THERAPIST: *Well, suppose one of your friends calls you up and invites you back to that restaurant. If you start telling yourself, “I might panic and pass out and*

people might make fun of me and that would be terrible,” . . . you might find you are dreading going to the restaurant, and you probably won’t enjoy the meal very much.

CLIENT: *Well, that is what usually happens.*

THERAPIST: *But it doesn’t have to be that way. . . . The way you feel, your reaction . . . depends on what you choose to believe or think, or say to yourself.* (Masters et al., 1987)

Cognitive-behavior therapists use many techniques related to rational-emotive behavior therapy to help clients learn to think and act in more adaptive ways. Behavioral techniques aimed at replacing upsetting thoughts with alternative thinking patterns were originally called *cognitive restructuring* (Lazarus, 1971). Using these techniques, clients plan calming thoughts that they can employ during exams, tense discussions, and other anxiety-provoking situations. The calming thoughts might take a form such as “OK, stay calm; you can handle this if you just focus on the task and don’t worry about being perfect” (Meichenbaum, 1977). Sometimes, the methods are expanded into *stress inoculation training*, in which clients imagine being in a stressful situation, then practice newly learned cognitive skills to remain calm (Meichenbaum, 1995).

Beck’s Cognitive Therapy Many behavior therapists seek a different kind of cognitive restructuring using Aaron Beck’s **cognitive therapy** (Beck, 1976, 1995; Beck & Beck, 1995). Beck’s treatment approach is based on the idea that certain psychological disorders—especially those involving depression and anxiety—can often be traced to errors in logic (e.g., “If I fail my driver’s test the first time, I will never pass it”), false beliefs (e.g., “Everyone ignores me”), and thoughts that minimize personal accomplishments (e.g., “Anyone could do that”). Beck says that over time, these learned *cognitive distortions* occur so quickly and automatically that the client never stops to consider that they might not be true.

Cognitive therapy is an active, structured, problem-solving approach in which the therapist helps clients notice how certain negative thoughts precede anxiety and depression (see Table 16.2). Then, much as in the five-step critical thinking system illustrated throughout this book, those thoughts and beliefs are treated as hypotheses to be tested rather than as assertions to be uncritically accepted. Accordingly, therapist and client take the role of “investigators” who develop ways to test beliefs such as “I’m no good around the house.” They might decide on tasks that the client will attempt as “homework”—such as cleaning out the basement, cooking a simple meal, paying bills, or cutting the grass. Success at accomplishing even one of these

Here are just a few examples of the kinds of thoughts that cognitive-behavior therapists see as underlying anxiety, depression, and other behavior problems. After reading this list, try writing an alternative thought that clients could use to replace each of these ingrained cognitive habits. Then jot down a “homework assignment” that you would recommend to help clients challenge each maladaptive statement, and thus develop new ways of thinking about themselves.

table 16.2

Some Examples of Negative Thinking

“I shouldn’t draw attention to myself.”

“I will never be any good at this.”

“It will be so awful if I don’t know the answer.”

“Everyone is smarter than I am.”

“Nobody likes me.”

“I should be able to do this job perfectly.”

“What if I panic?”

“I’ll never be happy.”

“I should have accomplished more by this point in my life.”

tasks provides concrete evidence to challenge a false belief that has supported depression, thus helping to reduce it (Beck et al., 1992). As therapy progresses, clients become more skilled at recognizing, and then correcting, the cognitive distortions related to their problems.

As mentioned in the chapter on psychological disorders, however, the cognitive roots of depression may involve more than specific thoughts and beliefs about certain situations. Depression may be associated with an overall cognitive style that leads people to expect that the worst will always happen to them and to assume that negative events occur because they are completely and permanently incompetent and worthless (Peterson, 1995; Peterson & Seligman, 1984). Accordingly, cognitive-behavior therapists also help depressed clients to develop more optimistic ways of thinking and to reduce their tendency to blame themselves for negative outcomes (Persons, Davidson, & Tompkins, 2001).

Group, Family, and Couples Therapy

Psychodynamic, humanistic, and behavioral treatments are often conducted with individuals, but they can also be adapted for use with groups of clients or with family units.

Group Therapy

Group therapy refers to the treatment of several unrelated clients under the guidance of a therapist who encourages helpful interactions among group members. Many groups are organized around a particular problem (such as alcoholism) or a particular type of client (such as adolescents). In most cases, six to twelve clients meet with their therapist at least once a week for about two hours. All group members agree to hold confidential everything that occurs during group sessions.

Group therapy offers several features not found in individual treatment (Yalom, 1995). First, group therapy allows the therapist to see clients interacting with one another. Second, clients discover that they are not alone as they listen to others and realize that many people struggle with difficulties at least as severe as their own. This realization tends to lift each client's expectations for improvement, a factor important in all forms of treatment. Third, group members can bolster one another's self-confidence and self-acceptance as they come to trust and value one another and develop group cohesiveness. Fourth, clients learn from one another. They share ideas for solving problems and give one another honest feedback about how each member "comes across." Fifth, perhaps through mutual modeling, the group experience makes clients more willing to share their feelings and more sensitive to other people's needs, motives, and messages. Finally, group therapy allows clients to try out new skills in a supportive environment.

Some of the advantages of group therapy are also put to use in *self-help*, or *mutual-help, organizations*. Self-help groups, such as Alcoholics Anonymous (AA), are made up of people who share some problematic experience and meet to help one another (Nowinski, 1999; Zimmerman et al., 1991). There are self-help groups for a wide range of problems, including alcohol and drug addiction, childhood sexual abuse, cancer, overeating, overspending, bereavement, compulsive gambling, and schizophrenia, among many others. The worldwide self-help movement has grown dramatically during the last two decades (Kurtz, 1997; O'Conner & Kratochwill, 1999), partly because many troubled people prefer to seek help from friends, teachers, or other "unofficial" helpers before turning to mental health practitioners (Swindle et al., 2000) and partly because some people have been dissatisfied with professional treatment. Dozens of self-help organizations operate through hundreds of thousands of local chapters, enrolling 10 million to 15 million participants in the United States and about half a million in Canada (Barlow et al., 2000; Norcross et al., 2000).

group therapy Psychotherapy involving several unrelated clients.

A Circle of Friends This meeting of Overeaters Anonymous is but one example of the self-help movement in North America, a rapidly growing network of inexpensive mental health and anti-addiction services offered by volunteer helpers, including friends and relatives of troubled people. A recent edition of one small-town Florida newspaper listed 104 local self-help groups focused on problems ranging from abuse to weight control. The services provided by nonprofessional groups like these make up about 20 percent of the total mental health and anti-addiction services offered in the United States (Borkman, 1997; Regier, Narrow, et al., 1993; Swindle et al., 2000).

Lack of reliable data makes it difficult to assess the value of many self-help groups, but available information suggests that active members may obtain some moderate improvement in their lives (Morganstern et al., 1997; Ouimette, Finney, & Moos, 1997). Some professional therapists view these groups with suspicion; others encourage clients to participate in them as part of their treatment or as a first step that might lead to more formal treatment (Haaga, 2000; Salzer, Rappaport, & Segre, 1999). This is especially true for clients with problems such as eating disorders, alcoholism, and other substance-related disorders (Dunne & Fitzpatrick, 1999).

Family and Couples Therapy

As its name implies, **family therapy** involves treatment of two or more individuals from the same family system, one of whom—often a troubled child or adolescent—is the initially identified client. The term *family system* highlights the idea that the problems displayed by one family member usually reflect problems in the entire family's functioning (Clarkin & Carpenter, 1995; Shlomo, 1999).

Ultimately, the family becomes the client, and treatment involves as many members as possible. In fact, the goal of family therapy is not just to alleviate the identified client's problems but also to create harmony and balance within the family by helping each member understand family interaction patterns and the problems they create (Goldenberg & Goldenberg, 1995). As with group therapy, the family format gives the therapist a chance to see how the initially identified client interacts with others, thus providing a basis for discussion of topics that are important to the family.

Family therapists who emphasize object relations theory point out that if the parents in a family have not worked out conflicts with their own parents, these conflicts will surface in relation to their spouses and children. Accordingly, these family therapy sessions might focus on the parents' problems with their own parents and, when possible, include members of the older generation (Nugent, 1994). A related approach, called *structural family therapy*, concentrates on family communication patterns (Minuchin & Fishman, 1981). It focuses on changing the rigid patterns and rituals that create alliances (such as mother and child against father) that perpetuate conflict and prevent the communication of love, support, or even anger.

family therapy Treatment of two or more individuals from the same family.

Many forms of couples therapy help partners improve communication through establishing rules such as these. Think about your own experience in relationships or your observations of couples as they interact, and then write down some rules you would add to this list. Why do you think it would be important for couples to follow the rules on your list?

table 16.3

Some “Rules for Talking” in Couples Therapy

1. Always begin with something positive when stating a problem.
2. Use specific behaviors rather than derogatory labels or overgeneralizations to describe what is bothersome about the other person.
3. Make connections between those specific behaviors and feelings that arise in response to them (e.g., “It makes me sad when you . . .”).
4. Admit your own role in the development of the problem.
5. Be brief; don’t lecture or harangue.
6. Maintain a focus on the present or the future; don’t review all previous examples of the problem or ask “why” questions, such as “Why do you always . . .?”
7. Talk about observable events; don’t make inferences about them (e.g., say, “I get angry when you interrupt me” rather than “Stop trying to make me feel stupid”).
8. Paraphrase what your partner has said, and check out your own perceptions of what was said before responding. (Note that this suggestion is based on the same principle as Rogers’s empathic listening.)

in review Approaches to Psychological Treatment

Dimension	Classical Psychoanalytic	Contemporary Psychodynamic	Humanistic	Behavioral/Cognitive-Behavioral
Nature of the human being	Driven by sexual and aggressive urges	Driven by the need for human relationships	Has free will, choice, and capacity for self-actualization	Is a product of social learning and conditioning; behaves on the basis of past experience
Therapist’s role	Neutral; helps client explore meaning of free associations and other material from the unconscious	Active; develops relationship with client as a model for other relationships	Facilitates client’s growth; some therapists are active, some are nondirective	Teacher/trainer who helps client replace undesirable thoughts and behaviors; active, action oriented
Focus	Emphasizes unresolved unconscious conflicts from the distant past	Understanding the past, but focusing on current relationships	Here and now; focus on immediate experience	Current behavior and thoughts; may not need to know original causes to create change
Goals	Psychosexual maturity through insight; strengthening of ego functions	Correction of effects of failures of early attachment; development of satisfying intimate relationships	Expanded awareness; fulfillment of potential; self-acceptance	Changes in thinking and behaving in particular classes of situations; better self-management
Typical methods	Free association; dream analysis; analysis of transference	Analysis of interpersonal relationships, including the client-therapist relationship	Reflection-oriented interviews designed to convey unconditional positive regard, empathy, and congruence; exercises to promote self-awareness	Systematic desensitization, modeling, assertiveness and social skills training, positive reinforcement, extinction, aversive conditioning, punishment, cognitive restructuring

Structural family therapists argue that when dysfunctional communication patterns are eliminated, problematic behaviors decrease because they are no longer necessary for survival in the family system.

Behavior therapists often use family therapy sessions as meetings at which family members can discuss and agree on behavioral “contracts.” Often based on operant conditioning principles, these contracts establish rules and reinforcement contingencies that help parents encourage their children’s desirable behaviors (and discourage undesirable ones) and help spouses become more supportive of each other (O’Farrell, 1995; Sanders & Dadds, 1993).

Therapists of many theoretical persuasions also offer **couples therapy**, in which communication between partners is the most important focus of treatment (Cordova & Jacobson, 1993). Discussion in couples therapy sessions is usually aimed at identifying and improving the miscommunication or lack of communication that is interfering with a couple’s happiness and intimacy. Often, the sessions revolve around learning to abide by certain “rules for talking,” such as those listed in Table 16.3. Some therapists also focus on helping couples to accept each other as a way of becoming closer, and behavior therapists even offer programs designed to prevent marital problems in couples who are at high risk for developing such problems (Berger & Hannah, 1999; Jacobson et al., 2000). One such program, called *behavioral premarital intervention*, not only helps engaged couples head off relationship problems but also prepares them to deal effectively with problems that might arise. (“In Review: Approaches to Psychological Treatment” summarizes key features of the main approaches to treatment that we have discussed so far.)

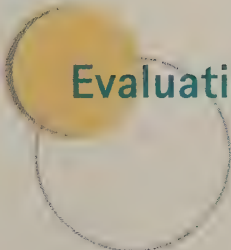

Evaluating Psychotherapy

Psychotherapy has been available for more than a hundred years, yet people are still asking if it works. Most psychotherapists and their clients believe in psychotherapy’s effectiveness (*Consumer Reports*, 1995); however, confirming this belief with experimental research has proved to be challenging and controversial (Brock, Green, & Reich, 1998; Dawes, 1994; DeRubeis & Crits-Christoph, 1998; Nathan, Stuart, & Dolan, 2000; Seligman, 1995, 1996).

The value of psychotherapy was first widely questioned in 1952, when British psychologist Hans Eysenck reviewed studies in which thousands of clients had received either traditional psychodynamic therapy, various other therapies, or no treatment. To the surprise and dismay of many therapists, Eysenck (1952) found that the percentage of clients who improved following any kind of psychotherapy was actually lower than that of people who received no treatment. Eysenck (1961, 1966) later supported his conclusions with additional evidence.

Critics argued that in drawing his conclusions, Eysenck had ignored studies that supported the value of psychotherapy and that he had misinterpreted his data (Bergin, 1971; de Charms, Levy, & Wertheimer, 1954; Luborsky, 1972). They pointed out, for example, that untreated clients may have been less disturbed than those in treatment, that untreated clients may have received informal treatment from their medical doctors, and that physicians who judged untreated clients’ progress might have used less demanding criteria than the psychotherapists who rated their own clients. In fact, when some of these critics conducted their own “box score” counts of successes and failures, they concluded that psychotherapy tends to be more helpful than no treatment (Bergin, 1971).

Debate over Eysenck’s findings—and the contradictory reports that followed them—highlighted several reasons why it is so difficult to definitively answer the apparently simple question, Does psychotherapy work? For one thing, there is the problem of how to measure improvement in psychotherapy. Should such assessment depend on psychological tests, behavioral observations, interviews, or a combination of all three? And what kinds of tests should be used? Where should clients be

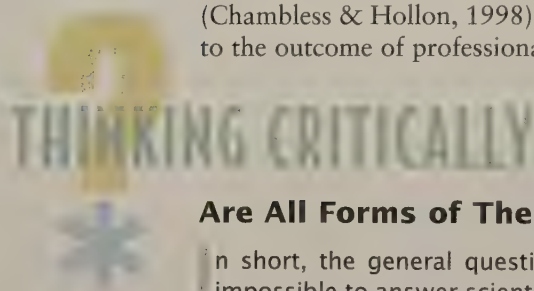

LINKAGES (a link to Introducing Psychology)

couples therapy A form of therapy focusing on improving communication between partners.

observed (and by whom)? And should equal weight be given to interviews with clients, friends, relatives, therapists, and teachers? The fact that all these measures tend to correlate only moderately with one another makes it that much harder for researchers to compare or combine the results of different studies and draw conclusions about the overall effectiveness of treatment (Lambert & Hill, 1994).

The question of effectiveness is further complicated by the broad range of clients, therapists, and treatments involved in the psychotherapy enterprise. Clients differ not only in terms of their problems but also in terms of their motivation to solve them. Therapists differ in skill, experience, and personality—and as we have seen, their treatment procedures can vary widely. To the extent that a client's improvement is influenced by all these factors, results from a study that evaluates one treatment may not apply to other clients and therapists (Kazdin, 1994b). Consider the example of a study in which “kindly college professors” were found to be as effective as experienced psychotherapists in helping people solve their problems (Strupp & Hadley, 1979). This result would appear relevant to the question of psychotherapy's effectiveness, but a careful reading of the study shows that the clients were college students with minor problems, not people with severe psychological disorders. Further, the fact that these students already had a relationship with their professors might have given the professors an edge over unfamiliar therapists (Chambless & Hollon, 1998). So the outcome of this study probably does not apply to the outcome of professional psychotherapy in general.

Are All Forms of Therapy Equally Effective?

In short, the general question of whether psychotherapy “works” is difficult or impossible to answer scientifically in a way that applies to all therapies for all disorders. However, the findings of several research reviews (Anderson & Lambert, 1995; Galatzer-Levy et al., 2000; Shadish et al., 2000; Smith, Glass, & Miller, 1980; Weisz & Jensen, 1999) have bolstered therapists' beliefs that psychotherapy does work (see Figure 16.3). In fact, most therapists believe that the theoretical approach and treatment methods they use are superior to those of other therapists (e.g., Giles, 1990). They can't all be right, of course, so what is going on?

● What am I being asked to believe or accept?

Some researchers argue that theories about the causes of psychopathology, and the specific treatment methods based on them, don't have much to do with the success of psychotherapy. All approaches, they say, are equally effective. This has been called the “Dodo Bird Verdict,” after the *Alice in Wonderland* creature who, when called upon to judge who had won a race, answered, “Everybody has won and all must have prizes” (Luborsky, Singer, & Luborsky, 1975).

LINKAGES (a link to Personality)

figure 16.3

An Analysis of Psychotherapy's Effects

These curves show the results of one large-scale analysis of the effects of psychotherapy. Notice that on average, people who received therapy for their problems were better off than 80 percent of troubled people who did not. The overall effectiveness of psychotherapy has also been confirmed in a more recent analysis of ninety treatment outcome studies (Shadish et al., 2000).

• What evidence is available to support the assertion?

Some evidence does suggest that there are no significant differences in the overall effectiveness of psychodynamic, humanistic, and behavioral therapies. Statistical methods, called *meta-analysis*, that combine the results of a large number of therapy studies have shown that the three treatment approaches are associated with about the same degree of success (Lambert & Bergin, 1994; Shadish et al., 2000; Smith, Glass, & Miller, 1980).

• Are there alternative ways of interpreting the evidence?

It is possible, however, that this evidence for the Dodo Bird Verdict is based on methods that cannot detect genuine differences among treatments. For example, a meta-analysis combining the results of many studies might not reveal important differences in the impact of particular treatments for particular problems (Eysenck, 1978; G. T. Wilson, 1985). It may also be that some specific techniques are more successful than others, but that when therapies are grouped by theoretical approach (psychodynamic, humanistic, or behavioral) rather than by specific procedures, the impact of those procedures might not be noticed (Giles, 1990; Marmar, 1990). For example, as described later, certain cognitive-behavioral techniques not used in other psychotherapy methods have been shown to be especially successful in the treatment of depression (DeRubeis & Feeley, 1990; DeRubeis et al., 1982; Feeley, DeRubeis, & Gelfand, 1999).

Further, differences among the effects of specific procedures might be overshadowed by the beneficial features shared by almost all forms of therapy—such as the support of the therapist, the hope and expectancy for improvement that therapy creates, and the trust that develops between client and therapist (Barber et al., 2000; Martin, Garske, & Davis, 2000). A therapist whose personal characteristics motivate a client to change might promote that change regardless of the therapeutic methods being used (Elkin, 1999; Hubble, Duncan, & Miller, 1999).

• What additional evidence would help to evaluate the alternatives?

The debate about whether all forms of psychotherapy are about equally effective on the average is likely to continue, but many researchers believe that it focuses on the wrong question. They believe that it is pointless to compare the effects of psychodynamic, humanistic, and behavioral methods in general. It is more important, they say, to address what Gordon Paul called the “ultimate question” about psychotherapy: “What treatment, by whom, is most effective for this individual with that specific problem, under what set of circumstances?” (Paul, 1969, p. 44).

• What conclusions are most reasonable?

Statistical analyses show that various treatment *approaches* appear to be about equally effective overall. But this does not mean that every specific psychotherapy method works in the same way, or that every psychotherapy experience will be equally beneficial. Potential clients must realize that the success of their treatment can still be affected by how severe their problems are, by the quality of the relationship they form with a therapist, and by the appropriateness of the therapy methods chosen for their problems.

Like those seeking treatment, many clinical psychologists, too, are eager for more specific scientific evidence about the effectiveness of particular therapies for particular kinds of clients and disorders. These empirically oriented clinicians are concerned that all too often, a therapist's choice of therapy methods depends more heavily on personal preferences or current trends than on scientific evidence of effectiveness (Davison, 1998; Nathan, Stuart, & Dolan, 2000). They believe that advocates of any treatment—whether it is object relations therapy or systematic desensitization—must demonstrate that its benefits are the result of the treatment itself and not just of the passage of time, the effects of repeated assessment, the

figure 16.4

Clinical Significance

Evaluations of psychological treatments must consider the clinical, as well as statistical, significance of observed changes. Here, the shaded area shows the range of deviant behaviors per minute displayed at home by normal boys. The solid line shows the average rate of deviant behaviors for boys in an operant conditioning treatment program for severe behavior problems. The improvement following reinforcement of appropriate behavior was not only statistically significant (compared with the pretreatment baseline) but also clinically significant, inasmuch as the once-deviant behavior came to resemble that of normal boys.

client's motivation and personal characteristics, or other confounding factors (Chambless & Hollon, 1998). They also want to see evidence that the benefits of treatment are *clinically significant*. To be clinically significant, therapeutic changes must be not only measurable but also substantial enough to make treated clients' feeling and actions similar to those of people who have not experienced these clients' disorders (Kendall, 1999; Kendall & Sheldrick, 2000). For example, a reduction in treated clients' anxiety test scores might be *statistically significant*, but if those clients do not now feel and act more like people without an anxiety disorder, the change is probably not clinically significant (see Figure 16.4). In recent years, the need to demonstrate the clinical significance of treatment effects has become clearer than ever as increasingly cost-conscious clients—and their health insurance companies—decide whether, and how much, to pay for various psychotherapy services (Dawes, 1994; Farberman, 1999).

By scientific tradition, the ideal way to evaluate treatment effects is through experiments in which clients are randomly assigned to various treatments or control conditions and their progress is objectively measured over time.

FOCUS ON RESEARCH METHODS

Which Therapies Work Best for Which Problems?

To help clinicians select treatment methods on the basis of that kind of empirical evidence, the American Psychological Association's Division of Clinical Psychology created a task force on effective psychotherapies (Task Force on Promotion and Dissemination of Psychological Procedures, 1995).

• What was the researchers' question?

The question addressed by this task force was "What therapies have proven themselves most effective in treating various kinds of psychological disorders?"

• How did the researchers answer the question?

Working with other empirically oriented clinical psychologists, members of this task force examined the outcomes of thousands of experiments that evaluated psychotherapy methods used to treat mental disorder, marital distress, and health-related behavior problems in adults, children, and adolescents (Baucom et al., 1998; Chambless & Ollendick, 2001; Compas et al., 1998; DeRubeis & Crits-Christoph, 1998; Kazdin & Weisz, 1998; Kendall & Chambless, 1998).

• What did the researchers find?

The task force found that a number of treatments—known as **empirically supported therapies**, or **ESTs**—have been validated by controlled experimental

LINKAGES (a link to Research in Psychology)

empirically supported therapies (ESTs)
Treatments whose effects have been validated by controlled experimental research.

table 16.4**Some Empirically Supported Therapies**

Problem	Efficacious and Specific	Efficacious	Possibly Efficacious
Major depressive disorder	Cognitive therapy	Behavior therapy; interpersonal therapy	Problem-solving therapy for depression
Generalized anxiety disorder	Cognitive therapy	Applied relaxation	
Social phobia	Exposure therapy; exposure plus cognitive restructuring		
Obsessive-compulsive disorder	Exposure and compulsive response prevention		Cognitive therapy
Agoraphobia	Exposure therapy		
Panic disorder	Panic control therapy; cognitive therapy	Exposure therapy; applied relaxation	
Posttraumatic stress disorder	Exposure therapy		Stress inoculation training; eye movement desensitization and reprocessing (see the chapter on research in psychology)
Schizophrenia			Social skills training
Alcohol abuse and dependence			Social skills training; cue exposure to drinking cues; cue exposure plus coping skills training
Substance dependence (Opiates)			Supportive-expressive therapy; cognitive therapy; behavior therapy (reinforcement)
(Cocaine)			Relapse prevention therapy

Treatments were listed by the American Psychological Association task force as "efficacious" (pronounced "eff-eh-KAY-shus"), or capable of helping clients, if they were superior to no treatment in at least two experiments by different research teams. Treatments listed as "efficacious and specific" were shown to produce clinically significant benefits that were superior to another form of therapy or a placebo control group. "Possibly efficacious" treatments have been found effective in only a single study or by a single research team (Chambless & Ollendick, 2001; DeRubeis & Crits-Christoph, 1998).

Source: DeRubeis & Crits-Christoph (1998).

research (DeRubeis & Crits-Christoph, 1998; Kendall & Chambless, 1998). As shown in Table 16.4, the therapies identified as effective for particular problems in adult clients are mainly behavioral, cognitive, and cognitive-behavioral methods, along with interpersonal therapy, a contemporary psychodynamic approach initially developed to treat depression (Klerman & Weissman, 1993; Markowitz & Swartz, 1997).

● What do the results mean?

The authors of the report on empirically supported therapies, as well as those who support their efforts, claim that relying on analysis of experimental research has constituted a scientific evaluation of various treatments and generated a list of methods from which clinicians and consumers can choose with confidence when facing specific disorders (e.g., Hunsley & Rumstein-McKean, 1999; Kendall & Chambless, 1998). Therapists are even being urged to follow the *treatment manuals* that were used in successful research studies to help them deliver empirically supported therapies exactly as they were intended (Addis, 1997; Wade, Treat, & Stuart, 1998).

Not everyone agrees with this interpretation or this recommendation. Critics argue that the list of empirically supported therapies is based on research that may not be relevant to clinicians practicing in the real world. They point out, for example, that experimental studies of psychotherapy have focused mainly on the therapeutic procedures used rather than on the characteristics and interactions of therapists and clients (Garfield, 1998; Hilliard, Henry, & Strupp, 2000). This emphasis on procedure is a problem, they say, because the outcome of therapy in these experiments might have been affected by whether the random assignment of clients to therapists resulted in a match or a mismatch on certain personal characteristics. These critics say that in real clinical situations, clients and therapists are not paired up at random (Hohmann & Shear, 2002; Persons & Silberschatz, 1998; Seligman, 1995). Finally, because therapists participating in experimental research were required to follow standard treatment manuals, they were not free to adapt treatment methods, as they normally would, to the needs of particular clients (Garfield, 1998). Perhaps, say these critics, when there is less experimental control over the treatment situation, all therapies are about equally effective, as suggested by the statistical analyses of outcome research we mentioned earlier (Shadish et al., 2000; Smith, Glass, & Miller, 1980).

In short, critics reject the empirically supported therapies list as a useful guide. In fact, some see it as an incomplete, irrelevant, and ultimately misleading document. They worry that it is based on research designed to evaluate treatment effects without adequately taking into account either the personal qualities and theoretical biases of those who offer therapy, or how those factors might interact with the characteristics of the clients who receive therapy (e.g., Henry, 1998). There is worry, too, that widespread use of treatment manuals would make psychotherapy too mechanical and less effective, and that it might suppress therapists' creativity in developing new treatment methods (Addis & Krasnow, 2000; Beutler, 2000; Garfield, 1998).

● What do we still need to know?

The efforts of the APA task force represent an important step in responding to Paul's (1969) "ultimate question" about psychotherapy: "What treatment, by whom, is most effective for this individual with that specific problem, under what set of circumstances?" We still have a long way to go, but—with research funding from the National Institute of Mental Health—empirically oriented clinical psychologists are determined to find scientific answers to this challenging question (Foxhall, 2000a). Their work will be focused not only on the efficacy of treatments in laboratory settings but also on the long-term effectiveness of treatment in more naturalistic situations (Nathan, Stuart, & Dolan, 2000; Westen & Morrison, 2001).

Addressing the "Ultimate Question"

The combinations of treatment methods and therapist and client characteristics that are best suited to remedying particular psychological problems have not yet been mapped out, but there are a few trends. For example, when differences show up in comparative studies of adult psychotherapy, they tend to reveal a small to moderate advantage for behavioral and cognitive-behavioral methods, especially in the treatment of phobias and certain other anxiety disorders (Barrowclough et al., 2001; Borkovec & Costello, 1993; DeRubeis & Crits-Christoph, 1998; Lambert & Bergin, 1994; Weisz et al., 1995), as well as bulimia nervosa, an eating disorder (Wilson, 1997). The same tends to be true for child and adolescent clients (Epstein et al., 1994; Weiss & Weisz, 1995; Weisz et al., 1995).

Further, the client-therapist relationship plays a consistent role in the success of all forms of treatment (Barber et al., 2000; Beutler, 2000; Brown & O'Leary, 2000; Elkin et al., 1999; Martin, Garske, & Davis, 2000). Certain people seem to be particularly effective in forming productive human relationships. Even without formal training, these people can sometimes be as helpful as professional therapists because

of personal qualities that are inspiring, healing, and soothing to others (Stein & Lambert, 1995). Their presence in self-help groups may well underlie some of the success of those groups and, among professionals, may help account for the success of many kinds of formal therapy. (It would be ideal if we could learn more about these people's qualities and, if possible, train others to develop them, too.)

Before choosing a therapist and treatment approach, then, clients should keep Paul's "ultimate question" in mind. They should carefully consider (1) what treatment approach, methods, and goals they find most comfortable and appealing; (2) information about the therapist's "track record" of clinically significant success with a particular method for treating problems similar to those they face; and (3) the likelihood of forming a productive relationship with the therapist. This last consideration assumes special importance when client and therapist do not share similar cultural backgrounds.

Cultural Factors in Psychotherapy

Imagine that after moving to an unfamiliar country to pursue your education or career, you become severely depressed. A friend there refers you to a therapist who specializes in depression. At your first session the therapist stares at you intently, touches your head for a moment, and says, "You have taken in a spirit from the river, and it is trying to get out. I will help." The therapist then begins chanting softly and appears to go into a trance. What would you think? Would you return for a second visit? If you are like most people raised in a Western culture, you probably wouldn't continue treatment, because this therapist probably does not share your beliefs and expectations about what is wrong with you and what should be done about it.

Similar sociocultural clashes can also occur within a particular country if clients bring to therapy a cultural or subcultural world view that is not shared by their therapist. For example, if a therapist assumes that a client's unexplained abdominal pain is a learned reaction to stress but the client is sure that it comes as punishment for having offended a long-dead ancestor, the client may not easily accept a treatment based on the principles of stress management (Wohl, 1995). In the United States, cultural clashes may be partly to blame for the underuse of, or withdrawal from, mental health services by recent immigrants, as well as by African Americans, Asian Americans, Hispanic Americans, American Indians, and members of other minority populations (Sue, 1998; U.S. Department of Health and Human Services, 2001a). Often the problem lies in mismatched goals. A therapist who believes that people should confront and overcome life's problems may encounter a client who believes that one should work at calmly accepting such problems (Sundberg & Sue, 1989). The result may be much like two people singing a duet using the same music but different lyrics (Johnson & Thorpe, 1994).

In other words, cultural differences, including religious differences, can create enough miscommunication or mistrust to threaten the quality of the client-therapist relationship. Major efforts are under way to ensure that cultural differences between clients and therapists do not interfere with the delivery of treatment to anyone who wants or needs it (Richards & Bergin, 2000; Sue et al., 1999). Virtually every psychotherapy training program in North America is seeking to recruit more students from traditionally underserved minority groups in order to make it easier to match clients with therapists from similar cultural backgrounds (e.g., Hammond & Yung, 1993; Sleek, 1999).

In the meantime, minority group clients are still likely to encounter a therapist from a differing background, so researchers are also examining the value of matching therapy techniques with clients' culturally based expectations and preferences (Hays, 1995; Preciado, 1994; Tanaka-Matsumi & Higginbotham, 1994). For example, many clients from collectivist cultures—in which the emphasis is on meeting the expectations of family and friends rather than satisfying personal desires—might

Preparing for Therapy Special pre-treatment orientation programs may be offered to clients who, because of cultural or subcultural factors, are unfamiliar with the rules and procedures of psychotherapy. These programs provide a pre-view of what psychotherapy is, how it can help, and what the client is expected to do to make it more effective (Sue, Zane, & Young, 1994).

expect to receive instructions from a therapist about how to overcome problems. How would such clients respond to a therapist whose client-centered treatment emphasizes more individualist goals, such as being independent and taking responsibility for the direction of change? David Sue and his students have investigated the hypothesis that the collectivist values of Asian cultures would lead Asians and Asian Americans to prefer a directive, problem-solving approach over nondirective, client-centered methods. Sue (1992) found that a preference for directive treatment was highest among foreign-born Asians compared with American-born Asians and European Americans. However, there are always individual differences; two individuals from the same culture may react quite differently to a treatment that group research suggests should be ideal for both of them. In Sue's (1992) study, for example, more than a third of the foreign-born Asians preferred the nondirective approach, and 28 percent of the European Americans preferred the directive approach.

Today, psychotherapists are more sensitive than ever to the cultural values of particular groups and to the difficulties that can impair intercultural communication (Carrillo & Lopez, 2001; Hall, 2001; Mishina, 1999; Shlomo, 1999). Some U.S. states now require clinical and counseling psychologists to complete courses on the role of cultural factors in therapy before being licensed. This training helps clinicians appreciate, for example, that it is considered impolite in some cultures to make eye contact with a stranger; this helps them recognize that clients from those cultures are not necessarily depressed, lacking in self-esteem, or inappropriately submissive just because they look at the floor during an interview. Graduate students are receiving similar training and practical experience as part of their course work in clinical or counseling psychology (Clay, 2001; Neville et al., 1996). Research with these students suggests that the training increases their sensitivity to cultural factors in treatment but does not necessarily increase their competence in actually working with members of ethnic minorities (Pope-Davis et al., 1995; Quintana & Bernal, 1995; Ramirez et al., 1996). Nevertheless, by providing a cultural extension of Rogers's concept of empathy, cultural sensitivity training helps therapists to appreciate the client's view of the world and thus to set goals that are in harmony with

that view (Sue, 1998; Yutrzenka, 1995). Minimizing the chances of cultural misunderstanding and miscommunication is one of the many ethical obligations that therapists assume whenever they work with a client (Tomes, 1999).

Rules and Rights in the Therapeutic Relationship

Treatment can be an intensely emotional experience, and the relationship established with a therapist can profoundly affect a client's life. Professional ethics and common sense require the therapist to ensure that this relationship does not harm the client. For example, the American Psychological Association's *Ethical Principles of Psychologists and Code of Conduct* forbids a sexual relationship between therapist and client—during treatment and for at least two years afterward—because of the severe harm it can cause the client (American Psychological Association, 1992b; Martin, 1999; Samuel & Gorton, 1998).

Ethical standards also require therapists, with a few exceptions, to keep strictly confidential everything a client says in therapy. Confidentiality is one of the most important features of a successful therapeutic relationship, because it allows the client to discuss unpleasant or embarrassing feelings, behaviors, or events without fear that the therapist might disclose this information to others. Professionals sometimes do consult with one another about their clients, but they are required not to reveal information to outsiders (including members of the client's family) without the client's consent. The next edition of the APA's code of ethics is sure to include new standards for protecting confidentiality for the growing number of clients who seek psychological services via *telehealth* channels, which include telephone, videophone, e-mail, or other Internet links (Budman, 2000; Foxhall, 2000b; Winzelberg et al., 2000). Among other things, these standards will probably require therapists to inform clients that others might be able to gain access to their e-mail messages, that no formal client-therapist relationship exists in e-mail exchanges, and perhaps that they should seek traditional therapy (Shapiro & Schulman, 1996).

Professional rules about confidentiality are backed up in most U.S. states by laws recognizing that information revealed in therapy—like information given to a priest, a lawyer, or a physician—is privileged communication. In 1996, a U.S. Supreme Court ruling also established psychotherapist-client privilege in the federal courts (DeBell & Jones, 1997; Knapp & VandeCreek, 1997). This means that by asserting *privilege*, a therapist can refuse, even in court, to answer questions about a client or to provide personal notes or tape recordings from therapy sessions. The law may require a therapist to violate confidentiality only under special circumstances, including those in which (1) the client is so severely disturbed or suicidal that hospitalization is needed, (2) the client uses his or her mental condition and history of therapy as part of a defense strategy in a civil or criminal trial, (3) the therapist must defend against the client's charge of malpractice, (4) the client reveals information about the sexual or physical abuse of a child or an incapacitated adult, and (5) the therapist believes the client may commit a violent act against a specific person.

The last condition poses a dilemma. Suppose a client says, "Someday I'm going to kill that brother of mine!" Should the therapist consider this a serious threat and warn the brother? In most cases, the danger is not real, but there have been tragic exceptions. For example, Prosenjit Poddar, a graduate student receiving therapy at the University of California at Berkeley in 1969, revealed his intention to kill Tatiana Tarasoff, a young woman whom he had dated the previous year but who later rejected him. The therapist took the threat seriously and consulted his supervisor and the campus police. It was decided that there was no real danger, so neither Tarasoff nor her parents were warned. After terminating therapy, the client killed Tarasoff. Her parents sued the university, the campus police, and the therapist. The parents won their case, thus setting an important precedent. Several U.S. states now have laws that make a therapist liable for failing to take steps to protect those who are threatened with violence by the therapist's clients (D.N. Bersoff, 1999). Other

Rights of the Mentally Ill In 1996, after years of odd behavior—including vague threats against government officials and claims that the government was spying on him through TV satellite dishes—Russell Eugene Weston, Jr., was diagnosed as displaying paranoid schizophrenia. He was hospitalized for seven weeks, but he had to be released when doctors determined that he was not a threat to himself or others as long as he took his prescribed medication. He failed to do so, however, and in July 1998, Weston killed two police officers during an armed rampage at the U.S. Capitol. Cases like his are frustrating to mental health professionals, whose decisions about hospitalization must balance the rights of mental patients against those of the public.

states allow therapists discretion in warning or protecting potential victims (Stromberg, Schneider, & Joondeph, 1993).

In the United States, people are protected from being casually committed to mental hospitals. Federal court decisions have given clients threatened with commitment the right to have written notice; an opportunity to prepare a defense with the help of an attorney; a court hearing, with a jury if desired; and the right to take the Fifth Amendment to avoid self-incrimination. Furthermore, before people can be forcibly committed, the state must provide “clear and convincing” evidence that they are not only mentally ill but also gravely disabled or an “imminent danger” to themselves or others. Most states now require a periodic review of every committed person’s records to determine whether release is appropriate.

While hospitalized, patients have the right to receive treatment, but they also have the right to refuse certain forms of treatment (Stromberg et al., 1988). These rules are designed to protect hospitalized mental patients from abuse, neglect, coercion, and exploitation, but they can also create difficulties and dangers. Consider Russell Eugene Weston, Jr., a former mental patient who was hospitalized after being charged with the murders of two police officers in 1998. Facing a possible death penalty but judged mentally incompetent to stand trial, he asserted his right to refuse drug treatment that would make him competent. After a long legal battle, Weston was forced to take medication. Prosecutors successfully argued that the right to refuse treatment does not extend to hospitalized patients who pose a danger to themselves or others.

Hospitalized patients who do not pose these dangers—including those whose dangerous impulses are being suppressed by drug treatment—have the right to be subjected to minimal restriction of their freedom. Accordingly, they are released from mental hospitals, usually with a supply of medication that they are to take on their own. Unfortunately, not all these patients follow doctors’ orders. Like Weston, Andrew Goldstein was not considered dangerous as long as he took his antipsychotic medication, but after being released from a New York City mental hospital in December 1998, he stopped doing so. About two weeks later, Goldstein pushed Kendra Webdale to her death under the wheels of a subway train. Cases like these cause the staffs of mental health facilities to worry about being sued if they keep a patient unnecessarily confined or if they release a patient who then harms someone. In an effort to strike a balance between the rights of mental patients and those of the public, several states now have laws requiring outpatient treatment for people who are dangerous when not medicated. The New York statute is known as Kendra’s Law.

Biological Treatments

Drugs that can ease the symptoms of psychological disorders are the latest in a long line of treatments based on the idea that psychological problems have physical causes. Hippocrates, a physician of ancient Greece, was among the first to propose this idea, and the treatments he prescribed included rest, special diets, laxatives, and abstinence from alcohol or sex. In the mental hospitals of Europe and North America during the sixteenth through eighteenth centuries, treatment of psychological disorders was based in part on Hippocrates’ formulations and consisted mainly of physical restraints, laxative purges, draining of “excess” blood, and induced vomiting. Cold baths, hunger, and other physical discomforts were also used in efforts to shock patients back to normality (Jones, 1923). Biological treatments for psychological problems have advanced considerably since then, but they remain somewhat controversial. Here we review the three main biological treatments that appeared in the twentieth century: brain surgery; electroconvulsive therapy; and psychoactive drugs, which are by far the most common form of medical treatment today.

Hospital Restraints Here are examples of the chains, straitjackets, belts, and covered bathtubs that were used to restrain disruptive patients in North American and European mental hospitals in the 1800s and well into the 1900s. These devices were gentle compared with some of the methods endorsed in the late 1700s by Benjamin Rush. Known as the “father of American psychiatry,” Rush advocated curing patients by frightening or disorienting them—for example, by placing them in a coffin-like box that was then briefly immersed in water.

Electroconvulsive Therapy

In the 1930s, a Hungarian physician named Ladislaus Von Meduna used a drug to induce convulsions in schizophrenics. He believed, incorrectly, that because schizophrenia and epilepsy rarely occur in the same person, epileptic-like seizures might combat schizophrenia. In 1938, Italian physicians Ugo Cerletti and Lucio Bini created seizures by passing an electric current through the brains of schizophrenia patients for one or two seconds. During the next twenty years or so, this procedure, called **electroconvulsive therapy (ECT)**, became a routine treatment for schizophrenia, depression, and sometimes mania. Upon awakening after an ECT session, the patient typically remembered nothing about the events just preceding the shock and experienced confusion. Although many patients improved, they often relapsed. The benefits of ECT also had to be weighed against its side effects, such as varying degrees of memory loss, speech disorders, and in some cases, death due to cardiac arrest or other problems (Lickey & Gordon, 1991; Shiwach, Reid, & Carmody, 2001).

To make ECT safer, patients are now given an anesthetic so that they are unconscious before the shock is delivered, along with a muscle relaxant to prevent bone fractures during convulsions. Also, the shock now lasts only about half a second and is usually delivered to only one side of the brain (e.g., Sackeim et al., 2000). Finally, in contrast to the dozens of treatments administered decades ago, patients now receive only about six to twelve shocks, one approximately every two days (Fink, 1999). Researchers have also recently begun experimenting with inducing seizures via repetitive transcranial magnetic stimulation (rTMS) instead of electrical shock (Lisanby et al., 2001; Wasserman & Lisanby, 2001).

Today, ECT is used mainly for patients with severe depression who do not respond to other treatments (Potter & Rudorfer, 1993; Rosenbach et al., 1997). It is also occasionally used with manic patients (e.g., Ciapparelli et al., 2001). ECT can be effective in such cases—especially when followed up with medication—and does not appear to cause brain damage (e.g., Ende et al., 2000; Sackeim et al., 2001; U.S. Surgeon General, 1999). However, no one knows for sure how ECT works (Rudorfer et al., 1997; Sackeim, 1994). Some suggest that it may somehow

electroconvulsive therapy (ECT) Brief electrical shock administered to the brain, usually to reduce depression that does not respond to drug treatments.

Electroconvulsive Therapy There are no national statistics on the use of ECT in the United States; estimates of the number of people receiving this treatment each year range from 30,000 to over 100,000 (Hermann et al., 1995). A survey in the United Kingdom suggests that about 12,000 patients a year are receiving ECT (U.K. Statistical Bulletin, 1999). Because of its dramatic and potentially dangerous nature, ECT remains a controversial method of treatment. Critics want it outlawed, but proponents of ECT argue that its benefits to certain patients outweigh its potential costs (Breggin, 1997; Fink, 1999).

improve neurotransmitter functions and thereby alter mood (Julien, 2001; Kapur & Mann, 1993). Another view is that the neurotransmitters that help the brain recover from convulsions also reduce activity in areas of the brain associated with depression, thus relieving it (Nobler et al., 2001; Sackeim, 1985). Because shock affects many aspects of brain function, identifying the specific mechanisms underlying ECT's effects on depression is exceedingly difficult (Abrams, 1997).

Psychosurgery

Procedures known as **psychosurgery** involve the destruction of brain tissue for the purpose of treating mental disorder. Among the first to try these procedures was a Portuguese neurosurgeon named António Egas Moniz. In 1935 he developed a technique, called *prefrontal lobotomy*, in which small holes are drilled in the skull, and a sharp instrument is inserted and moved from side to side (Freeman & Watts, 1942; Moniz, 1948). The theory was that emotional reactions in disturbed people become exaggerated due to neural processes in the frontal lobes and that the lobotomy disrupts these processes. During the 1940s and 1950s, psychosurgery became almost routine in the treatment of schizophrenia, depression, anxiety, aggressiveness, and obsessive-compulsive disorder (Valenstein, 1980). Unfortunately, brain surgery is risky, and sometimes fatal; its benefits are uncertain; and its side effects and complications, including epilepsy, are irreversible (Martin et al., 2001). Today, psychosurgery is performed only in rare cases in which all else has failed, and—guided by brain-imaging techniques—it focuses on much smaller brain areas than those involved in lobotomies (Dougherty et al., 2002; Feldman & Goodrich, 2001).

Psychoactive Drugs

The use of psychosurgery and ECT declined after the 1950s, not only because of their complications and general distastefulness but also because *psychoactive drugs* had begun to emerge as more convenient and effective treatment alternatives. In the chapters on biological aspects of psychology and on consciousness, we discuss how psychoactive drugs affect neurotransmitter systems and consciousness. Here, we describe how drugs are used to combat schizophrenia, depression, mania, and anxiety.

psychosurgery Surgical procedures that destroy tissue in small regions of the brain in an effort to treat psychological disorders.

Neuroleptics One group of drugs appearing in the early 1950s revolutionized the treatment of severe mental disorder. Called **neuroleptics** (or *antipsychotics*), these drugs dramatically reduced the intensity of psychotic symptoms such as hallucinations, delusions, paranoid suspiciousness, disordered thinking, and incoherence in many mental patients, especially those diagnosed with schizophrenia. As a result of taking these drugs, these patients became better able to care for themselves and more responsive to their environments. Thousands were able to leave the hospitals where they had been confined, some for many years. For those remaining, the drugs made straitjackets, padded cells, and other once-common restraints almost obsolete.

The most widely used neuroleptics are the *phenothiazines* (pronounced “fee-noh-THYE-uh-zeens”), of which the first, *chlorpromazine* (marketed as *Thorazine* in the United States and as *Largactil* in Canada and the United Kingdom), has been especially popular. Another neuroleptic called *haloperidol* (*Haldol*) is comparable to the phenothiazines in overall effectiveness, but it creates less sedation (Julien, 2001). Patients who do not respond to one of these neuroleptics may respond to the other. Between 60 and 70 percent of patients receiving these drugs show improvement, though fewer than 30 percent respond well enough to live entirely on their own.

Unfortunately, neuroleptics have problematic side effects, the mildest of which include dry mouth, blurred vision, urinary retention, dizziness, and skin pigmentation problems. More serious side effects include symptoms similar to those of Parkinson’s disease, such as muscle rigidity, restlessness, tremors, and slowed movement (Kane, 1989). Some of these side effects can be treated with medication, but the most serious, *tardive dyskinesia*, is an irreversible disorder of the motor system that appears only after years of neuroleptic use. Affecting at least 25 percent of patients who take chlorpromazine or haloperidol for several years, tardive dyskinesia involves grotesque, uncontrollable, repetitive movements of the body, often including tic-like movements of the face and thrusting of the tongue. Sometimes the person’s arms or legs flail unpredictably.

Among a newer generation of antipsychotic drugs (also called *atypical neuroleptics*) is *clozapine* (*Clozaril*), which has effects similar to those of the phenothiazines but does not cause movement disorders. Although no more effective on average than the phenothiazines, clozapine has helped many patients who did not respond to the phenothiazines or haloperidol, and it may reduce suicide risk in schizophrenia (Green & Patel, 1996; Rabinowitz et al., 2001). Unfortunately, for about 1 or 2 percent of those who take it, clozapine greatly increases the risk of developing a fatal blood disease called *agranulocytosis*, which is marked by the loss of white blood cells and consequent susceptibility to infectious disease (Alvir et al., 1993). Weekly blood tests are required to detect early signs of this disease, thus greatly increasing the cost of using clozapine (Meltzer, 1997).

Several other atypical antipsychotics have been introduced recently, including *risperidone* (*Risperdal*), *olanzapine* (*Zyprexa*) and *quetiapine* (*Seroquel*). These newer medications are expensive and are not free of side effects, but they do not cause agranulocytosis. Like clozapine, they also appear to reduce the “negative” symptoms of schizophrenia, such as lack of emotion, social withdrawal, and reduced speech (e.g., Azorin et al., 2001; Conley & Mahmoud, 2001; Volavka et al., 2002).

Antidepressants Soon after antipsychotic drugs appeared, they were joined by **antidepressants**, which, as their name suggests, were originally designed to relieve symptoms of depression. About 50 to 60 percent of patients who take these drugs show improved mood, greater physical activity, increased appetite, and better sleep. This degree of improvement is seen in only 10 to 20 percent of the most severe cases of psychotic depression, however (Agency for Healthcare Research and Quality, 1999; U.S. Surgeon General, 1999).

Curiously, although these drugs have almost immediate effects on neurotransmitters (usually increasing the availability of serotonin or norepinephrine), their

neuroleptics Drugs that alleviate the symptoms of severe disorders such as schizophrenia.

antidepressants Drugs that relieve depression.

effects on depressive symptoms do not occur for a week or two, and maximum effects take even longer. The mechanism underlying the effects of these drugs is consistent with some theories about the biology of depression discussed in the chapter on psychological disorders, but the time lag suggests that the effects occur through some sort of long-term compensatory process in the nervous system.

There are several classes of antidepressant drugs. The *monoamine oxidase inhibitors* (MAOIs) are effective in many cases of depression and in some cases of panic disorder, but they can produce severe hypertension if mixed with foods containing tyramine, a substance found in aged cheeses, red wine, and chicken livers (Julien, 2001). Fortunately, a new class of monoamine oxidase inhibitors is now available that does not carry this side effect risk (Julien, 2001).

Tricyclic antidepressants (TCAs) form another popular class of drugs for combating depression. The TCAs are prescribed more frequently than MAOI drugs because they seem to work somewhat better. They also have fewer side effects, though some patients stop taking tricyclics because of the sleepiness, dry mouth, dizziness, blurred vision, low blood pressure, constipation, and urinary retention they can cause. Further, the combination of tricyclics and alcohol can increase the effects of both, with potentially fatal results. Still, if side effects are controlled, tricyclics can be effective in cases of depression and can also reduce the severity and frequency of panic attacks in some cases of panic disorder.

Today, the most popular medications for depression are those that affect serotonin. The most prominent drug in this group is *fluoxetine* (Prozac). Introduced in 1986, fluoxetine quickly became the most widely used antidepressant in the United States. Its popularity is due to the fact that it is as effective as older antidepressants and, in most cases, has milder side effects (Cookson & Duffett, 1998; *Harvard Mental Health Letter*, 1998; Stokes, 1998). An improved version of Prozac, containing a purer active ingredient called R-fluoxetine, is currently being developed. Other, even newer antidepressants, including *venlafaxine* (Effexor), *nefazodone* (Serzone), and *bupropion* (Wellbutrin), show similar promise (Appleton, 2000; Croft et al., 1999; Quitkin et al., 2000).

Fluoxetine and other drugs that increase serotonin in the brain, such as *clomipramine* (Anafranil) and *fluvoxamine* (Luvox), are also effective in treating panic disorder and obsessive-compulsive disorder (Julien, 2001; Koran et al., 2002; U.S. Surgeon General, 1999).

Another development in the pharmacological treatment of depression is the use of an herbal remedy from a plant called Saint-John's-wort (*Hypericum perforatum*). In Germany, where this treatment is covered by health insurance, it is more popular than Prozac. One of the active ingredients in Saint-John's-wort is *hypericin*, a substance that, like Prozac, is thought to affect serotonin. Some studies have found Saint-John's-wort to be as effective as Prozac and other antidepressants, especially in treating milder forms of depression (e.g., Brenner et al., 2000; Gaster & Holroyd, 2000; Volz & Laux, 2000; Woelk, 2000). The design of these studies has been questioned, however (e.g., Spira, 2001), and in any case, treatment effects appear less impressive in cases of major depression (Shelton et al., 2001). Final conclusions about the safety and effectiveness of Saint-John's-wort must await the results of further research (Ernst, 2000; U.S. Surgeon General, 1999).

Lithium and Anticonvulsants Around 1970, it was discovered that a mineral salt of the element *lithium*, when taken regularly, could prevent both the depression and the mania associated with bipolar disorders in some patients. Administered as lithium carbonate, lithium is effective for 30 to 50 percent of patients with bipolar disorder (Baldessarini & Tondo, 2000; Manji, Bowden, & Belmaker, 2000; Zornberg & Pope, 1993). Without lithium, the typical bipolar patient has a manic episode about every fourteen months and a depressive episode about every seventeen months (Lickey & Gordon, 1991). With lithium, attacks of mania occur as rarely as every nine years (Bowden, 2000). The lithium dosage, however, must be

exact and carefully controlled; taking too much can cause nausea, vomiting, tremor, fatigue, slurred speech, and if the overdose is severe, coma or death. Further, lithium is not useful for treating a manic episode in progress because, as in the case of antidepressants, it takes a week or two of regular use before its effects are seen. So, as with the antidepressants, lithium's effects probably occur through some form of long-term adaptation as the nervous system adjusts to the presence of the drug.

In recent years, anticonvulsant drugs such as *divalproex* (*Epival* or *Depakote*) have been used as an alternative to lithium in treating mania. These drugs appear to cause fewer side effects, are less dangerous at higher doses, and are easier to regulate (Bowden et al., 2000; Hirschfeld et al., 1999).

Anxiolytics During the 1950s, a new class of drugs called *tranquilizers* was shown to reduce mental and physical tension and other symptoms of anxiety. The first of these drugs, called *meprobamate* (*Miltown* or *Equanil*), acts in a manner somewhat similar to barbiturates, meaning that overdoses can be fatal. Because they do not pose this danger, the *benzodiazepines*, particularly *chlordiazepoxide* (*Librium*) and *diazepam* (*Valium*), became the worldwide drug treatment of choice for anxiety (Blackwell, 1973). Today, these and other anti-anxiety drugs, now called **anxiolytics** (pronounced “ang-zee-oh-LIT-iks”), continue to be the most widely prescribed and used of all legal drugs. They have an immediate calming effect on anxiety and are quite useful in treating the symptoms of generalized anxiety disorder and posttraumatic stress disorder. One of the newest of the benzodiazepines, *alprazolam* (*Xanax*), has also become especially popular for the treatment of panic disorder and agoraphobia (Greenblatt, Harmatz, & Shader, 1993). Another benzodiazepine, *clonazepam* (*Klonopin*), is also being used, alone or in combination with other anxiolytics, in the treatment of anxiety ranging from phobias to panic disorder (Worthington et al., 1998). A number of antidepressant drugs, too—including *fluoxetine* (*Prozac*), *paroxetine* (*Paxil*), *clomipramine* (*Anafranil*), *fluvoxamine* (*Luvox*), and *sertraline* (*Zoloft*)—have also been found to be effective in treating anxiety-related problems such as panic disorder, social phobia, obsessive-compulsive disorder, and posttraumatic stress disorder in adults, and possibly in adolescents and children (Davidson et al., 2001; Todorov, Freeston, & Borgeat, 2000; Van Ameringen et al., 2001; Walkup et al., 2001).

Benzodiazepines can have bothersome side effects such as sedation, lightheadedness, and impaired psychomotor and mental functioning. Combining these drugs with alcohol can have fatal consequences, and continued use can lead to tolerance and physical dependence. After heavy or long-term use, attempts to stop taking benzodiazepines, particularly if the change is sudden, can result in severe withdrawal symptoms, including seizures and a return of anxiety more intense than the patient had initially experienced (Rickels et al., 1993).

An anxiolytic called *buspirone* (*BuSpar*) provides an alternative anxiety treatment that eliminates some of these problems, but it acts more slowly. As with the antidepressants, buspirone's effects do not occur for days or weeks after treatment begins; in fact, many patients stop taking it because they think it has no effect other than dizziness, headache, and nervousness (Lickey & Gordon, 1991). Yet buspirone can ultimately equal diazepam in reducing generalized anxiety (Schnabel, 1987; U.S. Surgeon General, 1999). Further, it does not seem to promote dependence, has fewer side effects than the benzodiazepines, and does not interact negatively with alcohol.

Table 16.5 lists the psychoactive drugs we have described, along with their uses, effects, and side effects.

Human Diversity and Drug Treatment So far, we have talked about drug treatment effects in general (“In Review: Biological Treatments for Psychological Disorders” summarizes our discussion of drugs and other biological treatments), but there can be significant differences among members of various ethnic groups and between men and women in terms of the psychoactive drug dose

anxiolytics Drugs that reduce feelings of anxiety.

table 16.5**A Sampling of Psychoactive Drugs Used for Treating Psychological Disorders****For Schizophrenia: Neuroleptics (Antipsychotics)**

Chemical Name	Trade Name	Effects and Side Effects
Chlorpromazine	Thorazine	Reduce hallucinations, delusions, incoherence, jumbled thought processes; cause movement-disorder side effects, including tardive dyskinesia
Haloperidol	Haldol	
Clozapine	Clozaril	Reduces psychotic symptoms; causes no movement disorders, but raises risk of serious blood disease
Risperidone	Risperdal	Reduces positive and negative psychotic symptoms without risk of blood disease

For Mood Disorders: Antidepressants and Mood Elevators**Tricyclics**

Imipramine	Tofranil	Act as antidepressants, but also have antipanic action; cause sleepiness and other moderate side effects; potentially dangerous if taken with alcohol
Amitriptyline	Elavil, Amitid	

Other Antidepressants

Fluoxetine	Prozac	Have antidepressant, antipanic, and anti-obsessive action
Clomipramine	Anafranil	
Fluvoxamine	Luvox	
Sertraline	Zoloft	

Other Drugs

Lithium carbonate	Carbolith, Lithizine	Calms mania; reduces mood swings of bipolar disorder; overdose harmful, potentially deadly
Divalproex	Depakote	Is effective against mania, with fewer side effects

For Anxiety Disorders: Anxiolytics**Benzodiazepines**

Chlordiazepoxide	Librium	Act as potent anxiolytics for generalized anxiety, panic, stress; extended use may cause physical dependence and withdrawal syndrome if abruptly discontinued
Diazepam	Valium	
Alprazolam	Xanax	Also has antidepressant effects; often used in agoraphobia (has high dependence potential)
Clonazepam	Klonopin	Is often used in combination with other anxiolytics for panic disorder

Other Anti-anxiety Agents

Buspirone	BuSpar	Has slow-acting anti-anxiety action; no known dependence problems
-----------	--------	---

Psychoactive drugs have been successful in dramatically reducing the symptoms of many psychological disorders. Critics point out that drugs can have troublesome side effects, however, and they may create dependence, especially after years of use (e.g., Breggin, 1997). They note, too, that drugs do not "cure" psychological disorders (National Institute of Mental Health, 1995) and that symptom relief may make some patients less likely to seek a permanent solution to their anxiety, depression, or other psychological problems.

necessary to produce clinical effects (U.S. Surgeon General, 1999). For example, Keh-Ming Lin, director of the Research Center on the Psychobiology of Ethnicity at the University of California at Los Angeles, has demonstrated that compared with Asians, Caucasians need to take significantly higher doses of the benzodiazepines, haloperidol, clozapine, lithium, and possibly the tricyclic antidepressants in order to obtain equally beneficial effects (Lin & Poland, 1995; Matsuda et al., 1996). In addition, African Americans may show a faster response to tricyclic antidepressants than European Americans and respond to lower doses of lithium (Strickland et al., 1991). There is also some evidence that compared with European Americans or African Americans, Hispanic Americans require lower doses of antipsychotic drugs to get the same benefits (Ruiz et al., 1999). Some of these ethnic differences are

in review**Biological Treatments for Psychological Disorders**

Method	Typical Disorders Treated	Possible Side Effects	Mechanism of Action
Electroconvulsive therapy (ECT)	Severe depression	Temporary confusion, memory loss	Uncertain
Psychosurgery	Schizophrenia, severe depression, obsessive-compulsive disorder	Listlessness, overemotionality, epilepsy	Uncertain
Psychoactive drugs	Anxiety disorders, depression, obsessive-compulsive disorder, mania, schizophrenia	Variable, depending on drug used: movement disorders, physical dependence	Alteration of neurotransmitter systems in the brain

thought to be a function of genetically regulated differences in drug metabolism, whereas others may be due to dietary practices.

Sex differences in drug response are also being investigated (e.g., Jensvold, 1996). In the past, much of our knowledge about drug effects in women—and about women's health in general—was based on studies of men. Because drug responses can differ in women and men, however, the male-oriented approach can be potentially dangerous for women. Fortunately, we are now seeing rapid growth in research focused specifically on matters relating to women's health, including their response to drugs (Vogeltanz, Sigmon, & Vickers, 1998). Some of this research suggests that women may maintain higher levels of therapeutic psychoactive drugs in their blood and show better response to neuroleptics, but they also may be more vulnerable to adverse effects such as tardive dyskinesia (Yonkers et al., 1992). It may be that hormonal and body-composition differences (such as the ratio of body fat to muscle) are among the factors responsible for sex differences in drug response (Dawkins & Potter, 1991; Yonkers et al., 1992). Continued research on these and other dimensions of human diversity will undoubtedly lead to more effective and safer drug treatments for psychological disorders (Thompson & Pollack, 2001).

Evaluating Psychoactive Drug Treatments

Despite the widespread success of psychoactive drugs in the treatment of psychological disorders, critics point out several problems with them. First, even if a disorder has physical components, drugs may mask the problem without curing it. This masking effect is desirable in treating otherwise incurable physical conditions such as diabetes, but it may divert attention from potentially effective nondrug approaches to psychological problems. For example, anti-anxiety drugs may be an aid to psychotherapy (Koenigsberg, 1994), but these drugs alone cannot teach people to cope with the source of their anxiety. Critics are concerned that psychiatrists, and especially general practitioners, rely too heavily on anxiolytics and other drugs to solve patients' psychological problems (Glenmullen, 2000). The antidepressant Prozac, for instance, is being widely prescribed—overprescribed, critics say—for problems ranging from hypersensitivity to criticism and fear of rejection to low self-esteem and premenstrual syndrome (Barondes, 1994). Second, abuse of some drugs (such as the anti-anxiety benzodiazepines) can result in physical or psychological dependence. Third, side effects present a problem. Some are merely annoying, such as the thirst and dry mouth produced by some antidepressants. Other side effects, such as tardive dyskinesia, are far more serious. Although these side effects occur in a minority of patients, some are irreversible, and it is impossible to predict in advance who will develop them.

Still, research on psychoactive drugs holds the promise of creating better drugs, a fuller understanding of the origin and nature of some psychological disorders, and

There is widespread concern that psychiatrists, and especially general practitioners, rely too heavily on drugs to deal with psychological problems. In one case, even a dramatic increase in medication failed to stop a paranoid schizophrenia patient from repeatedly running away from a mental hospital. But allowing him to use a telephone at a nearby shopping mall eliminated the problem. A psychologist discovered that the man had been afraid to use what he believed were “bugged” hospital phones and kept escaping to call his mother (Rabasca, 1999).

“I medicate first and ask questions later.”

more informed prescription practices. For example, advances in research on individual variations in the structure of the genes that create different types of dopamine receptors may explain why some schizophrenia patients respond to phenothiazines that bind primarily to one type of dopamine receptor, whereas others respond only to clozapine, which has a preference for another type of dopamine receptor (Van Tol et al., 1992). This research may guide the development of new drugs that are matched to specific receptors; the symptoms of schizophrenia then could be alleviated without the risk of movement disorders posed by the phenothiazines or the potentially lethal side effects of clozapine. Similarly, research on anxiolytics promises to reveal information about the chemical aspects of anxiety.

Drugs and Psychotherapy

We have seen that both drugs and psychotherapy can be effective in treating psychological disorders. Is one better than the other? Can they be effectively combined? A considerable amount of research is being conducted to address these questions.

Although occasionally a study does show that one approach or the other is more effective, there is no clear consensus; overall, neither form of therapy is clearly superior for treating problems such as anxiety disorders and major depressive disorder (Antonuccio, Danton, & DeNelsky, 1995). For example, large-scale studies of treatment for severe depression found that cognitive-behavior therapy was as effective as an antidepressant drug (DeRubeis et al., 1999). Cognitive-behavior therapy has also equaled drug effects in the treatment of phobias (Otto et al., 2000; Thom, Sartory, & Jöhren, 2000), panic disorder (Klosko et al., 1990), generalized anxiety disorder (Gould et al., 1997), and obsessive-compulsive disorder (Abramowitz, 1997; Kozak, Liebowitz, & Foa, 2000). Further, the benefits of many kinds of psychotherapy may last longer than those of drug therapies (e.g., Bovasso, Eaton, & Armenian, 1999; Segal, Gemar, & Williams, 2000; Thom, Sartory, & Jöhren, 2000).

What about combining drugs and psychotherapy? One research team compared the effects of gradual exposure treatment and an anti-anxiety drug (Xanax) in the treatment of agoraphobia. Clients receiving gradual exposure alone showed better short- and long-term benefits than those getting either the drug alone or a combination of the drug and gradual exposure (Echeburua et al., 1993). Other studies,

too, have found that combining drugs and psychotherapy may produce surprisingly little advantage (e.g., Elkin, 1994; Spiegel & Bruce, 1997). However, the combination of drugs and psychotherapy has been shown to be more effective than either method alone in treating certain disorders, including attention deficit hyperactivity disorder, obsessive-compulsive disorder, alcoholism, stammering, compulsive sexual behavior, panic disorder, and chronic depression (Barlow et al., 2000; deBeurs et al., 1995; Engeland, 1993; Keller et al., 2000; Reynolds et al., 1999). This combined approach may be especially helpful for clients who are initially too distressed to cooperate in psychotherapy (Kahn, 1995). Another approach, already found successful with clients who have been taking drugs for panic disorder, is to use psychotherapy to prevent relapse and make further progress as drug treatment is discontinued (e.g., Bruce, Spiegel, & Hegel, 1999).

It has been suggested that the most conservative strategy for treating anxiety and depression is to begin with cognitive or interpersonal psychotherapy (which have no major negative side effects) and then to add or switch to drug treatment if psychotherapy alone is ineffective. Often, clients who do not respond to one method will be helped by the other.

LINKAGES (a link to Biological Aspects of Psychology)

Biological Aspects of Psychology and the Treatment of Psychological Disorders

As noted in the chapter on biological aspects of psychology, human feelings, thoughts, and actions—whether normal or abnormal—are ultimately the result of biological processes, especially those in the brain, and most especially those involving neurotransmitters and their receptors. Alterations in the availability of these neurotransmitters, in the sensitivity of their receptors, and thus in the activity of the neural circuits they influence affect the ebb and flow of neural communication, the integration of information in the brain, and ultimately, behavior and mental processes. Because different neurotransmitters are especially prominent in particular brain regions or circuits (see Figure 3.22), altering the functioning of particular neurotransmitter systems will have relatively specific psychological and behavioral effects.

Some of the drugs that we have described for the treatment of psychological disorders were developed specifically to alter a neurotransmitter system that biological theories suggest might be involved in those disorders; in other cases, causal theories evolved from (often accidental) findings that drugs known to affect certain neurotransmitter systems help patients who display some disorder.

Let's consider in a little more detail some of the ways in which therapeutic psychoactive drugs affect neurotransmitters and their receptors. As described in the chapter on biological aspects of psychology, a given neuron can receive excitatory ("fire") or inhibitory ("don't fire") signals via neurotransmitters that facilitate or inhibit firing. Some therapeutic drugs amplify excitatory signals, whereas others increase inhibition. For example, the benzodiazepines (e.g., Valium and Xanax) exert their anti-anxiety effects by helping the inhibitory neurotransmitter GABA bind to postsynaptic receptors and, thus, suppress neuronal firing. This enhanced inhibitory effect acts as a sort of braking system that slows the activity of GABA-sensitive neurons involved in the experience of anxiety. However, benzodiazepines also slow the action of all neural systems that use GABA, including those associated with motor activity and mental processing, which are located throughout the brain. The result is the decreased psychomotor coordination and clouded thinking that appear as benzodiazepine's side effects.

Other therapeutic drugs reduce postsynaptic activity by serving as receptor antagonists (see Figure 9.12 in the consciousness chapter), acting to block the receptor site normally used by a particular neurotransmitter. Some neuroleptics—the phenothiazines and haloperidol, for example—exert their antipsychotic effects

LINKAGES (a link to Biological Aspects of Psychology)

by blocking receptors for dopamine, a neurotransmitter that, as described in the chapter on biological aspects of psychology, is important for movement. These drugs compete with dopamine, blocking the firing of neurons that normally use it. The fact that dopamine blockage can normalize the disordered thinking processes of many schizophrenics suggests that, as discussed in the chapter on psychological disorders, schizophrenia may be partly due to excess dopamine activity. Unfortunately, reducing this activity can create severe disorders—such as tardive dyskinesia—in the movement systems that are also controlled by dopamine.

Psychoactive drugs can also exert their therapeutic influence by increasing the amount of a neurotransmitter available at receptors, thereby maximizing the effects of that neurotransmitter. This enhanced availability can be accomplished either by stimulating production of the neurotransmitter or, as is more common in therapeutic drugs, by keeping the neurotransmitter in circulation in the synapse. Normally, after a neurotransmitter has been released, it flows back to the presynaptic terminal, where it is stored for later use. If this *reuptake* process is blocked, the neurotransmitter remains in the synapse, ready to work. The tricyclic antidepressants, for example, operate by blocking the reuptake of norepinephrine. Fluoxetine, clomipramine, and several other of the newer antidepressants are called *selective serotonin reuptake inhibitors* (or *SSRIs*) because they block the reuptake of serotonin. Others, such as venlafaxine, slow the reuptake of both serotonin and norepinephrine. These effects are consistent with biological theories suggesting that some cases of depression are traceable to faulty norepinephrine or serotonin systems.

Community Psychology: From Treatment to Prevention

It has long been argued that even if psychologists knew exactly how to treat every psychological problem, there would never be enough mental health professionals to help everyone who needs them (Albee, 1968). This view fostered the rise of **community psychology**, a movement that aims both to treat troubled people in their home communities and to promote social and environmental changes that can minimize or prevent psychological disorders.

One aspect of community psychology, the *community mental health movement*, arose during the 1960s as an attempt to make treatment available to people in their own communities. As antipsychotic drugs became available, and as concern grew that patients were not improving—and might be getting worse—after years of confinement in mental hospitals, thousands of these patients were released. The plan was that they would receive drugs and other mental health services in newly funded community mental health centers. This *deinstitutionalization* process did spare patients the boredom and isolation of the hospital environment, but the mental health services available in the community never matched the need for them. Some former hospital patients and many people whose disorders might once have sent them to mental hospitals are now living in halfway houses and other community-based facilities where they receive *psychosocial rehabilitation*. These community support services are designed not to “cure” them but to help them cope with their problems and develop the social and occupational skills necessary for semi-independent living (Hunter, 1995; Liberman et al., 1998). All too many others with severe psychological disorders are to be found enduring the dangers of homelessness on city streets or of confinement in jails and prisons (Ditton, 1999; U.S. Department of Health and Human Services, 2001a).

Community psychology also attempts to prevent psychological disorders by addressing unemployment, poverty, overcrowded substandard housing, and other stressful social problems that may underlie some disorders (Albee, 1985; Bracken &

community psychology A movement to minimize or prevent psychological disorders through changes in social systems and through community mental health programs.

Community Mental Health Efforts

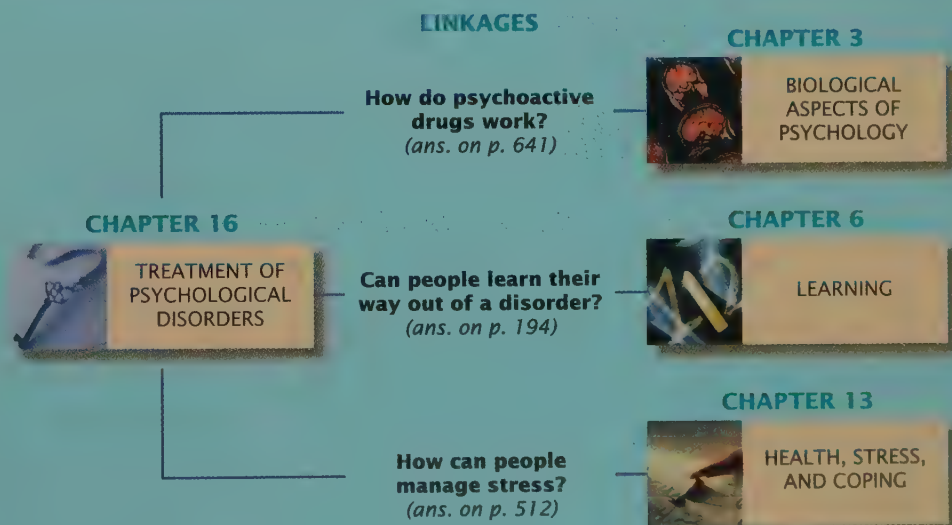

Professional and nonprofessional staff members of community mental health centers provide traditional therapy and mental health education, along with walk-in facilities or hotlines for people who are suicidal or in crises related to rape or domestic violence. They also offer day treatment to former mental patients, many of whom are homeless.

Thomas, 2001). Less ambitious, but perhaps even more significant, are efforts to detect psychological problems in their earliest stages and keep them from becoming worse, as well as to minimize the long-term effects of psychological disorders and prevent their recurrence (e.g., Dadds et al., 1997; Sanders et al., 2000). Examples include suicide prevention (Garland & Zigler, 1993); programs, including Head Start, that help preschoolers whose backgrounds hurt their chances of doing well in school and put them at risk for delinquency (Tremblay et al., 1995; Zigler, Taussig, & Black, 1992); identification of children who are at risk for disorder because of parental divorce or being rejected or victimized at school (e.g., Greenberg et al., 1999; Martinez & Forgatch, 2001); and interventions to head off anxiety or conduct disorders in children (August et al., 2001; Dadds et al., 1999).

LINKAGES

As noted in the chapter on introducing psychology, all of psychology's subfields are related to one another. Our discussion of treating psychological disorders through the use of psychoactive drugs illustrates just one way in which the topic of this chapter, the treatment of psychological disorders, is linked to the subfield of biological psychology (see the chapter on that topic). The Linkages diagram shows ties to two other subfields as well, and there are many more ties throughout the book. Looking for linkages among subfields will help you see how they all fit together and help you better appreciate the big picture that is psychology.

SUMMARY

Psychotherapy for psychological disorders is usually based on psychodynamic, humanistic, or social-cognitive (behavioral) theories of personality and behavior disorder. Most therapists combine features of these theories in an eclectic approach. The biological approach is reflected in the use of drugs and other physical treatment methods.

Basic Features of Treatment

All forms of treatment for psychological disorders include a client; a therapist; an underlying theory of behavior disorder; a set of treatment procedures suggested by the underlying theory; and the development of a special relationship between the client and therapist, which may make it easier for improvement to occur. Therapy may be offered to inpatients and outpatients in many different settings by *psychologists*, *psychiatrists*, and other mental health professionals. The goal of treatment is to help people change their thinking, feelings, and behavior so that they will be happier and function better. This goal may be pursued by promoting insight into hidden causes of behavior problems, by fostering personal growth through genuine self-expression, or by helping clients learn new ways of thinking and acting.

Psychodynamic Psychotherapy

Psychodynamic psychotherapy, which began with Sigmund Freud's methods of *psychoanalysis*, seeks to help clients gain insight into unconscious conflicts and impulses and then to explore how those factors have created disorders.

Classical Psychoanalysis

Exploration of the unconscious is aided by the use of free association, dream interpretation, and analysis of transference.

Contemporary Variations on Psychoanalysis

Some variations on psychoanalysis focus less on the id, the unconscious, and the past and more on helping clients harness the ego to solve problems in the present. Other forms of psychodynamic treatment retain most of Freud's principles but use a more flexible format. Object relations therapy, for example, examines the effects of early relationships with caregivers and how those relationships affect current ones.

Humanistic Psychotherapy

Humanistic (or phenomenological) psychotherapy helps clients to become more aware of discrepancies between their feelings and their behavior. According to the humanistic approach, these discrepancies are at the root of behavior disorders and can be resolved by the client once they are brought to light in the context of a genuine, trusting relationship with the therapist.

Client-Centered Therapy

Therapists using Carl Rogers's *client-centered therapy*, also known as *person-centered therapy*, help mainly by adopting attitudes toward the client that express *unconditional positive regard*, *empathy*, and *congruence*. These attitudes create a non-judgmental atmosphere that facilitates the client's honesty with the therapist, with himself or herself, and with others. One way of creating this atmosphere is through *reflection*.

Gestalt Therapy

Therapists employing the *Gestalt therapy* of Fritz and Laura Perls use more active techniques than do Rogerian therapists, often confronting and challenging clients.

Behavior Therapy

Behavior therapy, *behavior modification*, and *cognitive-behavior therapy* use learning principles to reduce clients' undesirable patterns of thought and behavior and to strengthen more desirable alternatives.

Techniques for Modifying Behavior

Common behavioral treatments include *systematic desensitization*, *modeling*, *assertiveness training*, and *social skills training*. More generally, behavior therapists use *positive reinforcement* (sometimes in a *token economy*), techniques based on *extinction* (such as *flooding*), *aversive conditioning*, and *punishment* to make desirable behaviors more likely or problematic behaviors less likely.

Cognitive-Behavior Therapy

Many behavior therapists also employ cognitive-behavior therapy to help clients alter the way they think, as well as the way they behave. Among the specific cognitive-behavior therapy methods are *rational-emotive behavior therapy (REBT)*, cognitive restructuring, stress inoculation training, and *cognitive therapy*.

Group, Family, and Couples Therapy

Therapists of all theoretical persuasions may offer therapy to several clients at once. Clients' interactions with one another can enhance the effects of treatment.

Group Therapy

Group therapy may involve a variety of people and problems, or it may focus on particular types of clients and problems. The group format is also adopted in many self-help, or mutual-help, organizations.

Family and Couples Therapy

Family therapy involves treatment of two or more individuals from the same family system. In *couples therapy*, the clients are

spouses or other people in intimate partnerships. In both formats, treatment usually focuses on improving communication and other interactions between and among the people involved.

Evaluating Psychotherapy

There is little agreement about exactly how to measure improvement following psychotherapy and how best to ensure that observed improvement was actually due to the treatment itself and not to some other factor. Meta-analyses have found that clients who receive psychotherapy are better off than most people who receive no treatment but that no single approach is uniformly better than all others for all clients and problems. Still, some methods appear effective enough in the treatment of particular disorders to have been listed by an American Psychological Association task force as *empirically supported therapies (ESTs)*.

Addressing the “Ultimate Question”

Research is needed to discover which combinations of therapists, clients, and treatments are ideally suited to alleviating particular psychological problems. Several factors, including personal preferences, must be considered when choosing a treatment approach and a therapist.

Cultural Factors in Psychotherapy

The effects of cultural differences in values and goals between therapist and client have attracted increasing attention. Efforts are under way to minimize the problems that these differences can create.

Rules and Rights in the Therapeutic Relationship

Whatever the specific form of treatment, the client's rights include the right to confidentiality; the right to receive or, sometimes, to refuse treatment; and the right to protection from unnecessary confinement.

Biological Treatments

Biological treatment methods seek to relieve psychological disorders by physical rather than psychological means.

Electroconvulsive Therapy

In *electroconvulsive therapy (ECT)*, an electric current is passed through the patient's brain, usually in an effort to relieve severe depression.

Psychosurgery

Psychosurgery procedures once involved mainly prefrontal lobotomy; when used today, usually as a last resort, they focus on more limited areas of the brain.

Psychoactive Drugs

Today the most prominent form of biological treatment is the prescription of psychoactive drugs, including drugs that are used to treat schizophrenia (the *neuroleptics*, or *antipsychotics*), mood disorders (*antidepressants*, lithium, and anticonvulsants), and anxiety disorders (*anxiolytics*). There appear to be significant differences among members of various ethnic groups and between men and women in the dosages of psychoactive drugs necessary to produce clinical effects.

Evaluating Psychoactive Drug Treatments

Psychoactive drugs have proven impressively effective in many cases, but critics point out a number of undesirable side effects associated with these drugs, the risks of abuse, and the dangers of overreliance on chemical approaches to human problems that might have other solutions.

Drugs and Psychotherapy

So far, neither psychotherapy nor drug treatment has been found clearly superior overall for treating problems such as anxiety or depression. Combining drugs and psychotherapy may help in some cases, but their joint effect may not be any greater than the effect of either one alone.

Community Psychology: From Treatment to Prevention

The realization that there will never be enough therapists to treat everyone who needs help prompted the development of *community psychology*. Community mental health programs and efforts to prevent mental disorders are the two main elements of community psychology.

Linkages**Summary**

At 8:48 A.M. on September 11, 2001, terrorists who had hijacked American Airlines Flight 11 crashed the plane into the north tower of New York City's World Trade Center. Fifteen minutes later, another team of hijackers flew United Airlines Flight 175 into the Trade Center's south tower. Both buildings ultimately collapsed. Forty-two minutes after the second crash, terrorists flew American Airlines Flight 77 into the Pentagon building, in Washington, D.C. Another target in Washington was spared only because courageous passengers on a fourth hijacked plane, United Airlines Flight 93, realized what was happening and attacked the hijackers. That plane crashed in a Pennsylvania field, killing all 45 people aboard. The loss of life in all 4 locations exceeded 3,000, the largest number of people to die violently on American soil in a single day since 1862, during the U.S. Civil War battle at Antietam.

Almost all of the questions being asked about this horrendous tragedy relate to human behavior. For example, what could lead people to kill themselves, along with thousands of innocent people, in the name of political or religious beliefs? Why did hundreds of firefighters, police officers, emergency medical workers, and others enter the World Trade Center's burning towers to save the lives of others while risking, and ultimately losing, their own? Why did some of the people who were fleeing the damaged buildings return to their offices after hearing an announcement telling them to do so? Is there any reason to hope that someday the hatred and distrust that brought about this disaster can be reduced or eliminated?

We may never have final answers to questions like these, but some partial answers may lie in the study of **social psychology**, the scientific study of how people's thoughts and feelings influence their behavior toward others, and how the behavior of others influences people's own thoughts, feelings, and behavior. In this chapter we focus on **social cognition**, the mental processes associated with the ways in which people perceive and react to other individuals and groups (Smith & Queller, 2001). Specifically, we will examine how people think about themselves and others, how they form and change attitudes, why and how they use stereotypes to judge other people (sometimes in unfair and biased ways), and why they like and dislike other people. In the chapter on *social influence*, we describe how social influences affect individuals, helping to shape behaviors that range from despicable acts of aggression to inspiring acts of heroism and self-sacrifice.

Social Influences on the Self

Each of us lives in both a private and a public world. You experience your thoughts and feelings privately, but they are products of the social and cultural environment, influenced by others in important ways, and they affect your public behaviors.

In the chapters on human development and personality, we describe how each individual develops within a cultural context, and the ways in which collectivist and individualist cultures emphasize different core values and encourage contrasting definitions of the self. In this section we look at the processes whereby the other people in the culture in which we live affect two important components of the self: **self-concept**, the beliefs we hold about who we are and what characteristics we have, and **self-esteem**, the evaluations we make about how worthy we are as human beings.

social psychology The study of how people's thoughts, feelings, and behavior influence, and are influenced by, the behavior of others.

social cognition Mental processes associated with people's perceptions of, and reactions to, other people.

self-concept The way one thinks of oneself.

self-esteem The evaluations people make about how worthy they are as human beings.

Social Comparison

People spend a lot of time thinking about themselves, trying to evaluate their own perceptions, opinions, values, abilities, and the like (Buunk & Oldersma, 2001). Decades ago, Leon Festinger (1954) noted that self-evaluation involves two distinct types of questions: those that can be answered by taking objective measurements and those that cannot. You can determine your height or weight by measuring it, but for

other types of questions—about mental ability, social skills, athletic prowess, or the quality of your relationships, for example—there are no objective criteria. In these cases, people make one of two types of comparisons: a **temporal comparison**, in which people consider their present condition in relation to how they were in the past (Wilson & Ross, 2000), or a **social comparison**, in which people evaluate themselves in relation to others. If you use others as a basis for evaluating how intelligent, interesting, or attractive you are, you are using social comparison (Oyserman, 2001).

Who serves as your basis of comparison? Festinger said that people usually look to others who are similar to themselves. For example, if you are curious about how good a swimmer you are, you are likely to compare yourself with the people against whom you compete, not with Olympic champions. That is, you tend to choose swimmers at your own level of experience and ability (Major, Sciacchitano, & Crocker, 1993). The categories of people to which you see yourself belonging and to which you habitually compare yourself are called **reference groups**.

The performance of people in a reference group can influence your self-esteem (Baumeister, 1998). For example, if being a good swimmer is very important to you, knowing that someone in your reference group swims much faster than you do can lower your self-esteem. People use a wide variety of strategies to protect or maintain their self-esteem (Leary, 2001; Tesser, 2001). Sometimes they choose to compare themselves with those who are not doing as well, a strategy called *downward social comparison*, but they may also engage in *upward social comparison*, comparing themselves to people who do much better (Wood, Michele, & Giordano, 2000). Both kinds of social comparisons can improve people's feelings about themselves and their situation. For example, distressed people may come to feel better when they compare themselves with those whose situation is worse than their own—a fact that helps account for the popularity of television talk shows that present unpleasant, and even bizarre, family situations. But they may also feel better after comparing themselves with those whose lives or relationships are better than their own (Buunk & Oldersma, 2001). This latter effect may occur partly because seeing people who are better off can create optimism about improving one's own situation (Buunk & Oldersma, 2001).

Some people use a related tactic to maintain their self-esteem during upward social comparison: telling themselves that a superior performer is not similar enough to be in their reference group. They may even exaggerate the ability of the other person so that their own performance doesn't look so bad when viewed in light of such an able competitor (Alicke et al., 1997). If you can convince yourself that you lost every point during a tennis match because your opponent is as good as Pete Sampras, Venus Williams, or some other world-class champion, then you can believe that your performance wasn't so terrible, and that you would do just fine against someone with normal athletic skills.

An unfavorable comparison of your own status with that of others can produce a phenomenon known as **relative deprivation**—the belief that no matter how much you are getting in terms of recognition, status, money, and so forth, it is less than you deserve (Corning, 2000). The concept of relative deprivation explains why an actor who receives \$5 million to star in a film feels abused if a co-star is receiving \$10 million. If an average person constantly identifies very wealthy people as a reference group, the resulting relative deprivation can make that person feel depressed and anxious (Taylor & Lobel, 1989). And if a large group experiences relative deprivation, political unrest may follow. Social and political turmoil usually begins after the members of a deprived group experience some improvement in their lives and begin to compare their circumstances with those in other groups (Worchel et al., 2000). With this improvement comes elevated expectations about what they deserve. When these expectations are not met, violence may follow. A feeling among citizens of poor countries that the United States enjoys and exploits its great prosperity may have played a role in creating the hatred that led to the attack on the World Trade Center, a symbol of U.S. financial strength.

temporal comparison Using one's previous performance or characteristics as a basis for judging oneself in the present.

social comparison Using other people as a basis of comparison for evaluating oneself.

reference groups Categories of people to which people compare themselves.

relative deprivation The belief that, in comparison to a reference group, one is getting less than is deserved.

The Muhammad Ali Effect When former heavyweight boxing champion Muhammad Ali was once asked why he did so poorly on an intelligence test, he replied, “I only said I was the greatest, not the smartest.” Recent research in the United States and in Holland suggests that most people, like Ali, consider it more important to be moral and honest than to be smart. They also believe that they are more honest than other people. This helps to maintain self-esteem (Van Lange & Sedikides, 1998).

FOCUS ON RESEARCH METHODS

Self-Esteem and the Ultimate Terror

Why is self-esteem so important to so many people? An intriguing answer to this question comes from the *terror management theory* proposed by Jeff Greenberg, Tom Pyszczynski, and Sheldon Solomon. This theory is based on the premise that humans are the only creatures capable of thinking about the future. One aspect of this ability is the realization that we will all eventually die, and the consequent experience of terror associated with it. We are unable to change this reality, but terror management theory suggests that humans cope with the anxiety it brings by developing a variety of self-protective psychological strategies, including efforts to establish and maintain high self-esteem (Greenberg, Pyszczynski, & Solomon, in press; Pyszczynski, Greenberg, & Solomon, 2001).

● What was the researchers' question?

In one series of experiments, Jeff Greenberg and his colleagues (1992) asked whether high self-esteem would, in fact, serve as a buffer against anxiety—specifically, the anxiety brought on by thoughts about death and pain.

● How did the researchers answer the question?

About 150 students at several North American universities participated in these studies, each of which followed a similar format. The first step in each experiment was to manipulate the independent variable, in this case the participants' self-esteem. To do this, the researchers gave the students feedback on a test they had taken earlier in the semester. Half the participants received feedback designed to increase their self-esteem (e.g., feedback that their scores indicated high intelligence or a stable personality). The other half received feedback that was neutral (i.e., neither flattering nor demeaning). Next, the students' self-esteem was measured to ensure that the positive feedback actually produced higher self-esteem than the neutral feedback (it did). In the third phase of each experiment, the researchers manipulated a second independent variable by provoking some anxiety in half of the participants in both the positive and neutral feedback groups. In one study, for example, anxiety was created by showing some students a film containing pictures of dead people and discussions of death. The others saw a neutral film that did not arouse emotion. In two other experiments, anxiety was created

by leading some of the participants to believe (falsely) that they would be receiving a mild electrical shock. Afterward, anxiety was measured by participants' self-reports or by monitoring galvanic skin resistance (GSR), a measure of perspiration in their skin that reflects anxiety-related physiological arousal (Dawson, Scheel, & Fillon, 2000).

● What did the researchers find?

Self-reports or GSR measures revealed that participants in all three experiments were significantly less upset by an anxiety-provoking experience (the death film or the threat of shock) if they had first received esteem-building feedback about their previous test performance.

● What do the results mean?

The researchers concluded that these results offer converging support for the notion that self-esteem is important as a buffer against anxiety and other negative feelings. The results help explain why the maintenance of self-esteem is such a powerful human motive (Tesser, 2001). People do not like to feel anxious, and increased self-esteem reduces most people's anxiety.

● What do we still need to know?

These results support terror management theory, but they are not broad enough in and of themselves to confirm all of its assumptions. For example, the theory also predicts that when people are sensitized to the threat of death, they will seek to protect themselves by suppressing thoughts of death, denying personal vulnerability, and doing things that increase their acceptance (and thus support) by others in the society where they live. Other studies by Greenberg and his colleagues (e.g., Pyszczynski, Greenberg, & Solomon, 1999; Greenberg et al., 2001) show that people do, indeed, use these strategies. Increased patriotism, for example, is a common response in people concerned about death, as has been evident in the United States long after the September 11, 2001, terrorist attacks. Reliance on religious faith is another widespread response.

But we still need to know which strategies people are most likely to use, and why. Are some strategies more or less likely to be adopted at different times in a person's life or among people in certain cultures? And what forms of self-esteem are most important in different cultures? So far, most of the research on terror management theory has been done in individualistic cultures such as North America, where self-esteem is largely based on personal accomplishments. In more collectivist cultures, feelings of self-worth tend to be more closely tied to the performance and status of the groups to which people belong (Miller, 2001). So far, there has been little or no research that explicitly looks at whether a more collectivist brand of self-esteem might also buffer the anxiety created by thoughts of death and other threats. In short, it will take many more experiments to test all the predictions derived from terror management theory, and some of that research is now under way by Greenberg and his colleagues.

Social Identity Theory

Stop reading for a moment, and fill in the blank in the following sentence: "I am a(n) _____."

Some people complete the sentence by using characteristics such as "hard worker," "good sport," or some other aspect of their *personal* identity. However, many others identify themselves by using a word or phrase that reflects their nationality, gender, or religion. These responses reflect **social identity**, our beliefs about the groups to which we belong. Our social identity is thus part of our self-concept (Troop & Wright, 2001).

Our social, or group, identity permits us to feel part of a larger whole (Deaux & Martin, 2001). Its importance is seen in the pride that people feel when a member of

TRY THIS

social identity The beliefs we hold about the groups to which we belong.

All in the Family Many people find that their place in their family is a central aspect of their social identity. For others, their role in a political, religious, cultural, or business organization might be most vital to that identity. Whatever the specifics, social identity is an important part of people's self-concept, or view of themselves.

their family graduates from college or when a local team wins a big game (Burris, Branscombe, & Klar, 1997). In wars between national, ethnic, or religious groups, individuals make sacrifices, and even die, for the sake of their group identity. A group identity is also one reason people donate money to those who are in need, support friends in a crisis, and display other helping behaviors toward those with whom they can identify. As we will see later, however, defining ourselves in terms of a group identity can foster an “us-versus-them” mentality that sets the stage for prejudice, discrimination, intergroup conflict, and even terrorism (Brewer, 2001).

Self-Schemas

Through social comparison and the formation of a social identity, people develop **self-schemas**, which are mental representations of their beliefs and views about themselves (Kenrick, Neuberg, & Cialdini, 2002). Like our social identity, self-schemas become part of our self-concept. Some people's self-schemas are relatively *unified*; they think of themselves as having more or less the same characteristics or attributes in every situation (at home, at a party, and so on) and in every role (as student, friend, or romantic partner). Other individuals have *differentiated* self-schemas; they think of themselves as having different attributes in different roles or situations.

Variations in the way people think about themselves have a strong impact on their emotional experiences (Clark, 1994). For example, students with unified self-schemas are likely to have an especially strong emotional reaction to failing an exam, because they would tend to interpret failure in this one area as implying incompetence in all areas (Niedenthal, Setterlund, & Wherry, 1992). After failing, they are likely to lower their opinions of themselves not only as students but also in a variety of other roles—as sons or daughters, for example. In contrast, people with more differentiated self-schemas may think less of themselves as students after failing an exam, but that failure will have fewer implications for the way they think of themselves in their other social roles (Kihlstrom & Klein, 1994).

Self-schemas contain information not only about what people are like at the moment but also about what they could be like in the future. Recognition of this *future self* or *possible self* can be a source of motivation to try harder to do better

self-schemas Mental representations that people form of themselves.

at various tasks. In one study, people who were told to think of themselves as successful at work persisted longer on a difficult task than people who were told to think of themselves as failing at work (Ruvolo & Markus, 1992). Unfortunately, feelings of depression can result in people who perceive an insurmountable discrepancy between their present selves and some desired future self (Higgins, Vookles, & Tykocinski, 1992; Taylor, Peplau, & Sears, 2000).

Social Perception

There is a story about a company president who was having lunch with a man being considered for an executive position. When the man salted his food without first tasting it, the president decided not to hire him. The reason, she explained, was that the company had no room for a person who acted before collecting all relevant information. The candidate lost his chance because of **social perception**, the process through which people interpret information about others, form impressions of them, and draw conclusions about the reasons for their behavior. In this section we examine how and why social perception influences our thoughts, feelings, and actions.

The Role of Schemas

The perception of people follows many of the same laws that govern the perception of objects, including the Gestalt principles discussed in the chapter on perception. Consider Figure 17.1. Consistent with Gestalt principles, most people would describe it as “a square with a notch in one side,” not as eight straight lines (Woodworth & Schlosberg, 1954). The reason is that they interpret new information using the mental representations, or *schemas*, they already have about squares; in short, they interpret this diagram as a square with a slight modification.

Schemas about people, too, can have a significant influence on our perception of them, because first of all, schemas influence what we pay attention to and what we ignore. Characteristics or events that are consistent with our schema about another person usually get more attention than those that are inconsistent with that schema. Accordingly, we tend to process information about the other person more quickly if it confirms our beliefs about that person’s gender or ethnic group than if it violates those beliefs (Smith & Queller, 2001). Second, schemas influence what we remember about others. One study demonstrated that if people thought a woman they saw in a videotape was a waitress, they recalled that she had a beer with dinner and owned a TV set; if they thought she was a librarian, they remembered that she was wearing glasses and liked classical music (Cohen, 1981). Finally, schemas affect our judgment about the behavior of others (Fiske, 1995). Thomas Hill and his colleagues (1989) found that participants’ ratings of male and female friends’ sadness were influenced not only by the friends’ actual behavior but also by the participants’ general schemas about how much sadness men as opposed to women tend to experience.

In other words, through “top-down” processing, schemas can influence—and sometimes bias—person perception in the same manner in which schemas about objects can affect object perception. And just as they help us read sentences in which words have missing letters, schemas also allow us to efficiently “fill in the blanks” about people. Accordingly, medical patients and bus passengers do not usually ask their doctors or drivers for credentials. Their schemas about these people lead to perceptions that the person who examines them or drives their bus is competent, confident, skilled, and experienced. And usually these perceptions are correct. It is only when our expectations are violated that we realize that schemas can create errors in our judgment about other people.

figure 17.1

A Schema-Plus-Correction

People who see an object like this tend to use a pre-existing mental representation (their schema of a square) and then correct or modify it in some way (here, with a notch).

May I Help You? Schemas help us quickly categorize people and respond appropriately to them, but they can also create narrow-mindedness and, as we will see later, prejudice. If this woman does not fulfill your schema—your mental representation—of how carpenters are supposed to look, you might be less likely to ask her advice on your home improvement project. One expert carpenter who manages the hardware department of a large home improvement store told us that most customers walk right past her in order to ask the advice of one of her less-experienced male clerks.

First Impressions

The schemas we have about people act as lenses that shape our first impression of them. That impression, in turn, influences both our perceptions of their behavior and our reactions to that behavior. First impressions are formed quickly, usually change slowly, and typically have a long-lasting influence. No wonder first impressions are so important in the development of social relations (Smith & Mackie, 2000). How do people form impressions of other people? And why are they so resistant to change?

TRY THIS

Forming Impressions Think about your first impression of a close friend. It probably formed rapidly, because as mentioned earlier, existing schemas create a tendency to automatically infer a great deal about a person on the basis of limited information (Smith & Queller, 2001). An ethnic name, for example, might have caused you to draw inferences about your friend's religion, food preferences, or temperament. Clothing or hairstyle might have led you to make assumptions about your friend's political views or taste in music. These inferences and assumptions may or may not have been accurate; how many turned out to be true in your friend's case?

One schema has a particularly strong influence on our first impressions: the assumption that most people we meet hold attitudes and values similar to our own (Hoyle, 1993). All else being equal, then, we are initially inclined to like other people. However, it does not take much negative information to change our minds. The main reason for this is that most of us don't expect other people to act negatively toward us. When unexpectedly negative behaviors do occur, they capture our attention and lead us to believe that these behaviors reflect something negative about the other person (Taylor et al., 2000). For example, we know that there are many reasons why people might behave positively around us—because they are nice, they like us, they want to sell us insurance, our best friend likes them, and so on, but a negative act suggests to us only that they are unfriendly or have other undesirable personality traits (Coovert & Reeder, 1990). In short, negative behavior carries more weight in shaping first impressions than does positive information (Smith & Mackie, 2000).

social perception The processes through which people interpret information about others, draw inferences about them, and develop mental representations of them.

Noticeable features or actions help shape our impressions of others, which may or may not be correct.

DILBERT reprinted by permission of United Feature Syndicate, Inc.

Lasting Impressions Does your friend seem the same today as when you met? First impressions can change, but the process is usually very slow. One reason is that humans tend to be “cognitive misers” (Fiske, 1995). We maintain our existing beliefs about the world, often using our schemas to preserve a reality that fits our expectations. Holding on to existing impressions appears to be part of this effort. If your friend has recently said or done something that violates your expectations, your view of her probably did not change much, if at all. In fact, you may have acted to preserve your impression by thinking something like, “She is not herself today.” In other words, impressions are slow to change because the meaning we give to new information about people is shaped by what we already know or believe about them (Sherman & Klein, 1994).

Self-Fulfilling Prophecies Another reason first impressions tend to be stable is that we often do things that cause others to confirm our impressions (Kenrick, Neuberg, & Cialdini, 2002). If teachers expect particular students to do poorly in mathematics, the students may sense this expectation, exert less effort, and perform below their ability level. In therapy, counselors can draw extraverted behavior from clients whom they believe to be extraverted, whether or not they actually are (Copeland & Snyder, 1995). When, without our awareness, schemas

Self-Fulfilling Prophecies in the Classroom

As discussed in the chapter on cognitive abilities, first impressions of a student's potential can alter a teacher's behavior. If teachers inadvertently spend less time helping children who impressed them as “dull,” those children may not learn as much, thus fulfilling the teachers' expectations. If the girl in the back row has not impressed this teacher as being bright, how likely do you think it is that she will be called on?

cause us to subtly lead people to behave in line with our expectations, a **self-fulfilling prophecy** is at work.

In one experiment on self-fulfilling prophecies, men and women participated in “get-acquainted” conversations over an intercom system. They could not see each other, but before the conversations took place, the men were shown photographs and told that they were pictures of their partners. Some saw a photograph of an obese woman, whereas others saw a picture of a woman of normal weight. In fact, the photographs bore no relationship to the women’s actual appearance. Independent judges who had not seen any of the participants listened to tapes of the ensuing conversations and rated the women’s behavior and personalities. The women who had been described as being of normal weight were judged as more articulate, lively, interesting, exciting, and fun to be with. Apparently, when the men thought their partners were of normal weight, they were more friendly and engaging, and this behavior drew more positive reactions from the women. In contrast, men who thought their partners were overweight behaved in ways that drew comparatively dull responses (Snyder & Haugen, 1995).

Self-fulfilling prophecies also help maintain judgments about groups. If you assume that members of a certain ethnic group are pushy or aggressive, for example, you might display defensiveness or even hostility toward them. Faced with this behavior, members of the group might become frustrated and angry. Their reactions would thus fulfill your prophecy and perpetuate the impressions that created it (Ross & Jackson, 1991).

Explaining Behavior: Attribution

So far, we have considered how people form impressions about the characteristics of other people. But perceptions of others include another key element: explanations of behavior. People tend to form *implicit theories* about why people (including themselves) behave as they do and about what behavior to expect in the future. Psychologists use the term **attribution** to describe the process people go through to explain the causes of behavior (including their own).

As an example, suppose a classmate fails to return borrowed notes on time. You could attribute the behavior to many causes, from an unanticipated emergency to simple selfishness. Which of these alternatives you choose is important because it will help you to *understand* your classmate’s behavior, *predict* what will happen if this person asks to borrow something in the future, and decide how to *control* the situation should it arise again. Similarly, whether a person attributes a spouse’s nagging to stress-induced irritability or to lack of love can influence whether that person will work on the marriage or work to dissolve it.

People tend to attribute behavior in a particular situation to either primarily internal causes (characteristics of the person) or primarily external (situational) causes (Aronson et al., 2002). For example, if you thought your classmate’s failure to return notes was due to lack of consideration or laziness, you would be making an *internal attribution*. If you thought that the oversight was due to time pressure caused by an upcoming exam or a family crisis, you would be making an *external attribution*. Similarly, if you failed an exam, you could explain it by concluding either that you’re not very smart (internal attribution) or that your work schedule left you too little time to study (external attribution). The attribution that you make, in turn, might determine how much you study for the next exam or even whether you decide to stay in school.

self-fulfilling prophecy A process through which an initial impression of someone leads that person to behave in accordance with that impression.

attribution The process of explaining the causes of people’s behavior, including one’s own.

Sources of Attributions Harold Kelley (1973) proposed an influential theory of how people (whom Kelley called *observers*) make attributions about the actions of other people (whom Kelley called *actors*). To illustrate this theory, suppose you are at home for the weekend. You want to invite your friend Ralph to stay for dinner, but your father says no. According to Kelley, understanding the reasons

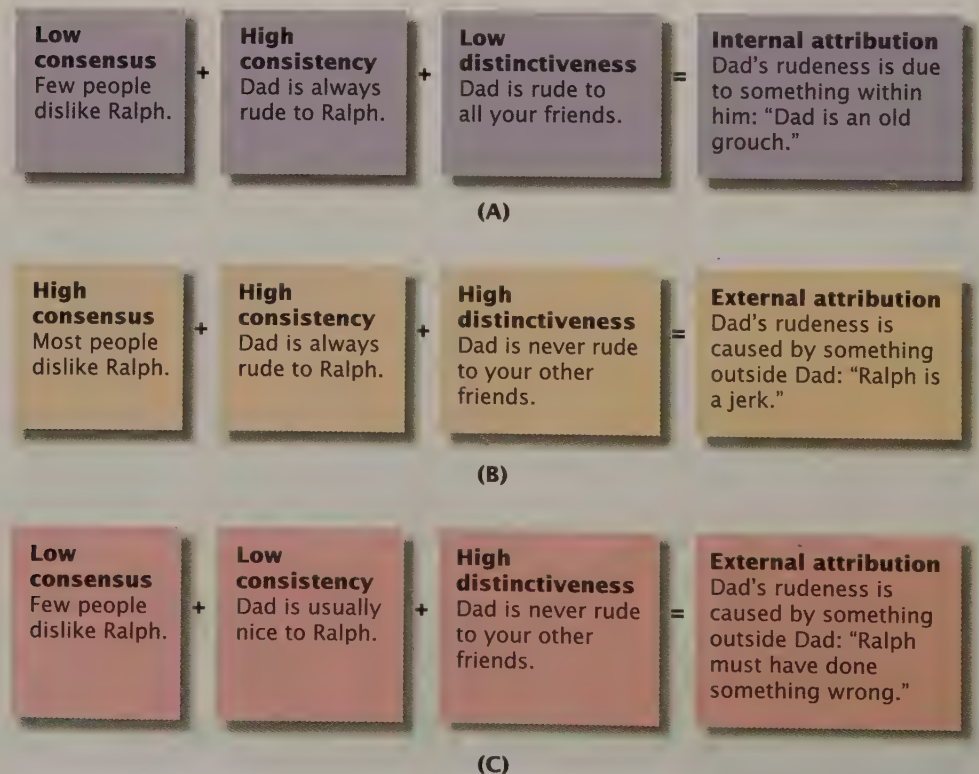

for your father's behavior requires information about three key variables: consensus, consistency, and distinctiveness (Kelley, 1973):

1. **Consensus** is the degree to which other people's behavior is similar to that of the actor—in this case, your father. If everyone you know avoids Ralph, your father's behavior has a high degree of consensus, and you would attribute his reaction to an external cause (probably something about Ralph). However, if everyone else likes being with Ralph, your father's negative response would have low consensus. Accordingly, you would probably attribute it to something about your father, such as his being a grouch or his personal dislike for Ralph.
2. **Consistency** is the degree to which the behavior is the same across time and/or situations. If your father has invited Ralph to dinner several times in the past but rejects him this time, the consistency of his behavior is low. Low consistency suggests that your father's behavior is attributable to external causes, such as the fact that Ralph has just returned from a camping trip and hasn't showered for two weeks. Conversely, if your father's behavior toward Ralph is always hostile, it has high consistency. But is your father's consistent behavior attributable to an internal cause (his consistent grouchiness) or to an external cause (Ralph's consistent offensiveness)? This question is difficult to answer without information about distinctiveness.
3. **Distinctiveness** concerns the extent to which similar stimuli draw the same behaviors from the actor. If your father is nasty to all your friends, his behavior toward Ralph has low distinctiveness. Behavior that is low in distinctiveness is usually attributable to internal causes, such as enduring personality traits. However, if your dad gets along with everyone except Ralph, his behavior has high distinctiveness, and your attribution about the cause of his behavior is likely to shift toward a cause other than your father's personality, such as how Ralph acts (or smells).

figure 17.2

Causal Attribution

Here are the most common patterns of consensus, consistency, and distinctiveness that lead people to attribute other people's behavior to internal or external causes.

In summary, Kelley's theory suggests that people are most likely to make internal attributions about an actor's behavior when there is low consensus, high consistency, and low distinctiveness. If you observe your boss insulting customers (a situation of low consensus, inasmuch as most people in business are polite to customers) every day (high consistency) no matter who the customers are (low distinctiveness), you would probably attribute this behavior to the boss's personality rather than to some external cause such as the weather or the customers' rudeness. But if you saw the boss on just one day (low consistency) being rude (low consensus) to one particular customer (high distinctiveness), you would be more likely to attribute the incident to the customer's behavior or some other external factor. External attributions are often made in response to other information patterns as well, as Figure 17.2 illustrates.

Culture and Attribution Most theories of causal attribution were developed by North American psychologists who implicitly assumed that the same kinds of information lead to internal or external attributions all over the world. However, there is substantial evidence to suggest that this may not be true. For example, Joan Miller and David Bersoff (1994) found that students from the United States and students from India made very different attributions about the reasons why people would do a favor for someone who had just helped them. The Americans attributed the behavior to an external cause (feeling an obligation to repay a favor), but the Indians attributed it to an internal cause (liking to help people). Miller (1994) suggested that the differences in the two groups' responses reflected differences in their cultural experiences. The results of Miller and Bersoff's experiment highlight once again the danger of assuming that phenomena seen in European American cultures generalize to all cultures. Cross-cultural differences in attribution and other aspects of social cognition may help to explain why people in different cultures sometimes have so much difficulty in understanding one another.

Biases in Attribution

Whatever their background, most people are usually logical in their attempts to explain behavior (Trope, Cohen, & Alfieri, 1991). However, they are also sometimes prone to *attributional biases* that can distort their view of behavior (Gilbert, 1998).

Why Are They Helping? Helping occurs all around the world, but research shows that people's attributions, or explanations, about why it happens can differ from culture to culture.

Attributional Bias Men whose thinking is colored by the ultimate attribution error might assume that women who succeed at tasks associated with traditional male gender roles are just lucky, but that men succeed at those tasks because of their skill (Deaux & LaFrance, 1998). When this attributional bias is in operation, people who are perceived as belonging to an out-group, whether on the basis of their gender, age, sexual orientation, religion, ethnicity, or other characteristics, may be denied fair evaluations and equal opportunities.

The Fundamental Attribution Error North American psychologists have paid special attention to something they call the **fundamental attribution error**, a tendency to overattribute the behavior of others to internal factors, such as personality traits (Gilbert & Malone, 1995). Imagine that you hear a student give an incorrect answer in class. You are liable to attribute this behavior to an internal cause and assume that the person is not very smart. In doing so, however, you might be failing to consider the possible influence of various external causes (such as lack of study time).

A related form of cognitive bias is called the *ultimate attribution error*, in which both positive actions by members of an *out-group* (people we perceive as different) and negative actions by members of an *in-group* (people with whom we identify) are attributed to external situational factors rather than internal personal ones (Pettigrew, 1979). Because of the ultimate attribution error, members of the out-group receive little credit for their positive actions, and members of the in-group get little blame for their negative actions. Biases such as the ultimate attribution error help maintain people's negative views of out-groups and positive views of their own in-group (Fiske, 1998).

In recent years some psychologists have questioned the impact and pervasiveness of the fundamental attribution error (Sabini, Siepmann, & Stein, 2001). For example, they point out cross-cultural studies showing that the attributional tendencies seen Europeans and North Americans are not universal. People in collectivist cultures, such as India, China, Japan, and Korea, are less likely than those in the individualist cultures of North America and Europe to attribute people's behavior to internal causes; rather, they tend to see behavior as due to an interaction between individual characteristics and the situations or contexts in which the person is immersed (Miller, 2001; Norenzayan & Nisbett, 2000). There are also individual differences in attributional tendencies among people within Euro-American cultures. According to one study, for example, people raised in the southern United States are more inclined than northerners to make external attributions (Sims & Baumann, 1972).

Researchers also point out that when people from collectivist cultures do erroneously attribute other people's behaviors to internal causes, it is not necessarily because they fail to consider situational factors or other external influences on those behaviors. It may simply be that, given the information available, an internal attribution appears to be the most reasonable cognitive choice under the circumstances (Sabini, Siepmann, & Stein, 2001). Further, David Funder has argued that under many circumstances, we are capable of making quite accurate judgments of what people are like and what motivates them (Funder, 2001).

Other Attributional Biases The inclination toward internal attributions is much less pronounced when people explain their own behavior. Here, in fact, another bias tends to come into play: the **actor-observer bias**. Whereas people often attribute other people's behavior to internal causes, they tend to attribute their own behavior to external factors, especially when the behavior is inappropriate or inadequate (Baumeister, 1998). For example, when you drive slowly, it is because you are looking for an address, not because you are a dimwitted loser like that jerk who crawled along in front of you yesterday.

The actor-observer bias occurs mainly because people have different kinds of information about their own and others' behavior. When *you* are acting in a situation—giving a speech, perhaps—the stimuli that are most noticeable to you are likely to be external and situational, such as the temperature of the room and the size of the audience. You also have a lot of information about other external factors, such as the amount of time you had to prepare your talk or the upsetting argument that occurred this morning. If your speech is disorganized and boring, you can easily attribute it to one or all of these external causes. But when you observe someone else, the most noticeable stimulus in the situation is *that person*. You do not know

fundamental attribution error A bias toward overattributing the behavior of others to internal causes.

actor-observer bias The tendency to attribute other people's behavior to internal causes while attributing one's own behavior (especially errors and failures) to external causes.

what happened to the person last night or this morning, so you are likely to attribute whatever he or she does to enduring internal characteristics (Gilbert, 1998).

Of course, people do not always attribute their own behavior to external forces. In fact, the degree to which they do so depends on whether the outcome of their behavior is positive or negative. In one study, researchers asked each of several students to work with a partner on a task and then, regardless of their actual performance, told half of the pairs that they had succeeded and half that they had failed. Students who were told that their team was successful took personal credit for the success; those who had supposedly failed blamed their partner (Sedikides et al., 1998). These students showed a **self-serving bias**, the tendency to take personal credit for success but to blame external causes for failure.

The Self-Protective Functions of Social Cognition

The self-serving bias occurs partly because, as noted earlier, people are motivated to maintain their self-esteem—and ignoring negative information is one way to do so. If you just failed an exam, it is painful to admit that your grade was fair, so you might blame your performance on an unreasonably demanding instructor. Other forms of social cognition also help people think about their failures and shortcomings in ways that protect their self-esteem (Tesser, 2001).

Unrealistic optimism is one example. Unrealistic optimism is the tendency to believe that positive events (such as financial success or having a gifted child) are more likely to happen to oneself than to others, and that negative events (such as being in an accident or having cancer) are more likely to happen to others than to oneself (Krueger, 1998; see “In Review: Some Biases in Social Perception”).

Unrealistic optimism is fueled, in part, by another self-protective form of social cognition called *unique invulnerability*. For example, when motorcyclists in England were asked to estimate the chances that they would be in a serious traffic accident during the next twelve months, virtually all of them said that this was far less likely to happen to them than to other motorcycle riders (Rutter, Quine, & Albery, 1998).

in review Some Biases in Social Perception

Bias	Description
Importance of first impression	Ambiguous information is interpreted in line with a first impression, and the initial schema is recalled better and more vividly than any later correction to it. Actions based on this impression may elicit behavior that confirms it.
Fundamental attribution error	The tendency to attribute the behavior of others to internal factors.
Actor-observer bias	The tendency for actors to attribute their own behavior to external causes and for observers to attribute the behavior of others to internal factors.
Self-serving bias	The tendency to attribute one's successes to internal factors and one's failures to external factors.
Unrealistic optimism	The tendency to assume that positive events are more likely, and negative events are less likely, to occur to oneself than to others.

self-serving bias The tendency to attribute one's successes to internal characteristics while blaming one's failures on external causes.

Unrealistic optimism tends to persist even in the face of evidence that contradicts it, and it can lead to potentially harmful behaviors. This phenomenon was illustrated by a study that found that people who were unrealistically optimistic about their health exercised infrequently and knew relatively little about how to prevent heart disease (Davidson & Prkachin, 1997).

Note that *unrealistic* optimism differs from the generally optimistic (but realistic) perspective on life that, as mentioned in the chapter on health, stress, and coping, is positively correlated with good physical and mental health. Unrealistic optimism can have the opposite effects. For example, one reason why people may engage in risky sexual behaviors (e.g., unprotected sex with multiple partners) is that they estimate the risks of unsafe sex to be much lower for themselves than for other people (Taylor et al., 1992).

Self-protective cognitive biases can help us temporarily escape from something painful, but they also set the stage for a somewhat unrealistic view of reality and, in the long run, can create problems. Like the defense mechanisms described in the chapter on personality, cognitive strategies such as unrealistic optimism may temporarily decrease anxiety and blunt the impact of stress. These strategies, though, may also keep people from taking the rational steps necessary for long-term protection of their health, well-being, and safety (Ayanian & Cleary, 1999).

Attitudes

People's views about health or safety reflect their *attitudes*, an aspect of social cognition that social psychologists have studied longer and more intensely than any other. An **attitude** is the tendency to think, feel, or act positively or negatively toward objects in our environment (Ajzen, 2001; Eagly & Chaiken, 1998). Attitudes are believed to play an important role in guiding how we react to other people, what political causes we support, which products we buy, and countless other daily decisions.

The Structure of Attitudes

Social psychologists have long viewed attitudes as having three components (Schwarz & Bohnet, 2001; see Figure 17.3). The *cognitive* component is a set of beliefs about the attitude object. The emotional, or *affective*, component includes feelings about the object, and the *behavioral* component pertains to the way people act toward the object. Ideally, these components would be in harmony. We should be able to predict people's behavior in relation to preserving the natural environment, for example, on the basis of the thoughts or feelings they express and vice versa. This is often not the case, however (Bohner & Schwarz, 2001). Many people's positive thoughts and supportive emotions regarding the environment are never translated into actions aimed at, say, reducing pollution.

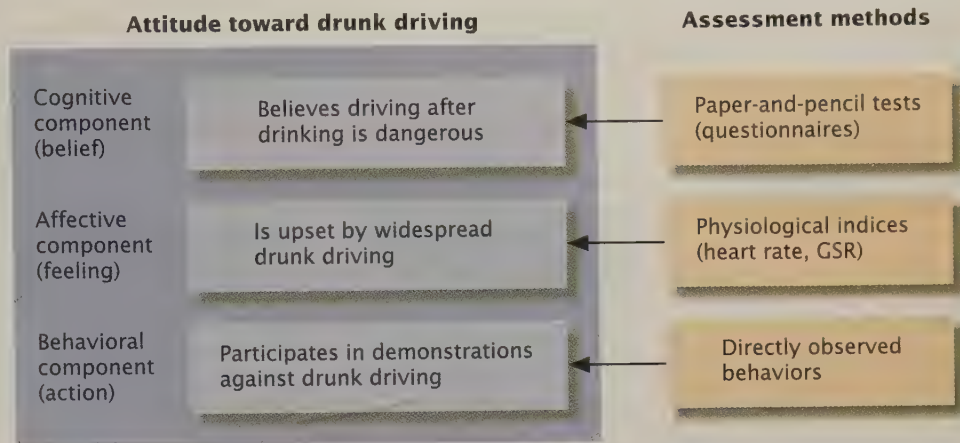

What determines whether people's behavior will be consistent with the cognitive and affective components of their attitudes? Several factors are important. For one thing, consistency is more likely when the cognitive and affective components are themselves in agreement (Lord, 1997). Second, consistency is more likely when the behavioral component of the attitude is in line with a *subjective norm*, our view of how important people in our lives want us to act. Conflict between attitudes and subjective norms may cause people to behave in ways that are inconsistent with their attitudes (Ajzen, 2001). For example, someone who believes that the rights of gay men and lesbians should be protected might not campaign for this cause because doing so would upset family members or co-workers who are against it. Third, attitude-consistent behavior is more likely when people have *perceived control*, the belief that they can actually perform such behavior (Ajzen & Fishbein, 2002). The cognitive and affective components of your attitude about protecting the envi-

attitude A predisposition toward a particular cognitive, emotional, or behavioral reaction to objects.

figure 17.3

Three Components of an Attitude

Various attitude components may or may not be consistent with one another. For example, people may deplore drunken driving (cognitive component) and be upset by its tragic consequences (affective component), yet not do anything to solve the problem. They may even get behind the wheel after drinking too much (behavioral component).

A Reminder about Poverty

Photographs like this one are used by fund-raising organizations to remind people of the kind thoughts and charitable feelings they have toward needy people and other social causes. As a result, people may be more likely to behave in accordance with the cognitive and affective components of their attitudes and make a donation to these good causes. Browse through several popular magazines, and calculate the percentage of such photos you find in ads for charitable organizations.

ronment may be positive, but if you don't believe you can do anything about it, you are not likely to even try. Fourth, *direct experience* with the attitude object increases the likelihood of attitude-consistent behavior (Bohner & Schwarz, 2001). This is because attitudes based on direct experiences are more stable and memorable and, thus, more likely to come into play when the attitude object is present. Accordingly, you might be more likely to actively support, and perhaps even participate in, efforts to clean up a polluted river if you have fished in it than if you have only heard of it in news reports.

This last explanation of the consistency or discrepancy among the components of attitudes reflects the cognitive theories described in the chapters on learning and memory. According to this view, attitudes reside in networks of cognitions—inter-connected evaluations and beliefs about attitude objects—that are stored in long-term memory (Tourangeau, Rips, & Rasinski, 2000; see also Figure 7.11 in the memory chapter). When you encounter an attitude object, the cognitions associated with it are activated. If your thoughts and feelings are well defined and come easily to mind, then your behavior is likely to be consistent with them; if not, there may be less consistency (Smith, 1998).

Forming Attitudes

People are not born with specific attitudes toward specific objects, but their attitudes about new objects begin to appear in early childhood and continue to emerge throughout life. How do attitudes form? As described in the chapters on human development and personality, inherited predispositions toward certain temperaments may create an indirect genetic basis for certain attitudes, but the formation of attitudes is influenced mainly by the principles of learning (Olson et al., 2001). In childhood, modeling and other forms of social learning are especially important. Children learn not only the names of objects but also what they should believe and feel about them and how they should act toward them. For example, a parent's words may teach a child not only that snakes are reptiles but also that they should be feared and avoided. So as children learn concepts such as "reptile" or "work," they learn attitudes about those concepts, too (Bohner & Schwarz, 2001).

Attitudes can also be influenced by classical and operant conditioning. In one study demonstrating this process, certain Pokémon cartoon characters were associated with positive words (e.g., *excellent*) and images (e.g., an ice cream sundae), whereas others were associated with negative words and images (Olson & Fazio, 2001). Afterward, participants in this study liked the characters associated with the positive stimuli much more than those associated with the negative ones. No wonder so many advertisers present enjoyable music or attractive images in association

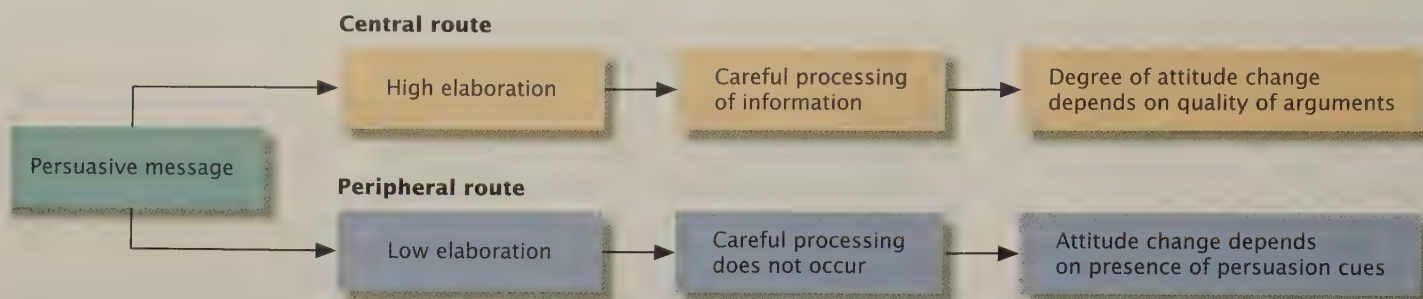

figure 17.4

The Elaboration Likelihood Model of Attitude Change

The central route to attitude change involves carefully processing and evaluating a message's content. The peripheral route involves reliance on persuasion cues, such as the attractiveness of the person making the argument, rather than on careful processing of the message (Cacioppo, Petty, & Crites, 1993).

with the products they are trying to sell (Aronson, Wilson, & Akert, 2002; Pratkanis & Aronson, 1991)! As for operant conditioning, parents, teachers, and peers actively shape children's attitudes by rewarding them for stating particular views. The *mere-exposure effect* is influential as well: All else being equal, attitudes toward an object will become more positive the more frequently people are exposed to it (Seamon et al., 1997; Zajonc, 2001b). One study found that even newborns showed a preference for the passages their mother had repeatedly read aloud while they were still in the womb (Cacioppo, Berntson, & Petty, 1997). The mere-exposure effect helps explain why we sometimes come to like a song only after hearing it several times—and why commercials and political ads are aired over and over.

Changing Attitudes

The nearly \$100 billion a year spent on advertising in the United States alone provides but one example of how people are constantly trying to change our attitudes. Stop for a moment and make a list of other examples, perhaps starting with the messages of groups concerned with abortion or recycling—and don't forget your friends who want you to think the way they do.

TRY THIS

Two Routes to Attitude Change

Whether a persuasive message succeeds in changing attitudes depends primarily on three factors: (1) the characteristics of the person communicating the message, (2) the content of the message, and (3) the audience who receives it (Bohner & Schwarz, 2001). The **elaboration likelihood model** of attitude change (illustrated in Figure 17.4) provides a framework for understanding when and how these factors affect attitude change. The model is based on the premise that persuasive messages can change people's attitudes through one of two main routes. The first is called the *peripheral route* because, when it is activated, we devote little attention to the actual content of the persuasive message and tend to be affected instead by the *persuasion cues* that surround it, such as the confidence, attractiveness, or other characteristics of the person delivering the message. Persuasion cues influence attitude change even though they say nothing about the logic or validity of the message content. Commercials in which movie stars or other attractive nonexperts endorse pain relievers are designed to operate via the peripheral route to attitude change. By contrast, when the *central route* to attitude change is activated, the content of the message becomes more important than the characteristics of the communicator in determining attitude change. A person following the central route uses logical steps—like those outlined in the Thinking Critically sections of this book—to rationally analyze the content of the persuasive message. This analysis considers the validity of the message's claims, determines whether the message leaves out pertinent information, assesses alternative interpretations of evidence, and so on.

elaboration likelihood model A model suggesting that attitude change can be driven by evaluation of the content of a persuasive message (central route) or by irrelevant persuasion cues (peripheral route).

cognitive dissonance theory A theory asserting that attitude change is driven by efforts to reduce tension caused by inconsistencies between attitudes and behaviors.

figure 17.5

Personal Involvement and Routes to Attitude Change

In the study represented here, students' level of agreement (+) or disagreement (-) with messages advocating exit exams for seniors depended on whether they thought the policy would begin immediately (high involvement) or only after they had graduated (low involvement). In the low-involvement condition, students followed a peripheral route to attitude change, agreeing with messages from highly credible communicators regardless of how strong or weak the arguments were. Students who were more involved followed a central route, changing their minds only if the message contained a strong, logical argument.

Source: Data from Petty, Cacioppo, & Goldman (1981); Petty, Cacioppo, & Schumann (1983).

What determines which route people will follow? Personal involvement with message content is one important factor. The elaboration likelihood model proposes that the more personally involving a topic is, the more likely the central route will be activated (Petty & Wegener, 1998; Wood, 2000). Suppose, for example, that you heard someone advocating the termination of student loans in Chile. This message might persuade you via the peripheral route if it came from someone who looked attractive and sounded intelligent. However, you would be more likely to follow the central route if the message proposed terminating student loans at your own school. You might be persuaded, but only if the logic of the message was irrefutable (see Figure 17.5). This is why celebrity endorsements tend to be most effective when the products being advertised are relatively unimportant to the audience.

"Cognitive busyness" is another factor affecting which attitude-change route is activated. If you are busy thinking about other things while a message is being delivered, you will be unable to pay much attention to its content—in which case activation of the peripheral route becomes more likely. Personality characteristics are also related to attitude-change processes. For example, people with a strong *need for cognition* like to engage in thoughtful mental activities and are therefore more likely to use the central route to attitude change (Suedfeld & Tetlock, 2001). In contrast, people whose discomfort with uncertainty creates a *need for closure* are more likely to use the peripheral route (Cacioppo et al., 1996).

Persuasive messages are not the only means of changing attitudes. Another approach is to get people to act in ways that are inconsistent with their current attitudes, in the hope that they will adjust those attitudes to match their behavior. Often, such adjustments do occur. Cognitive dissonance theory and self-perception theory each attempt to explain why.

Cognitive Dissonance Theory Leon Festinger's (1957) classic *cognitive dissonance theory* holds that people want their thoughts, beliefs, and attitudes to be consistent with one another and with their behavior. When people experience inconsistency, or *dissonance*, among these elements, they become anxious and are motivated to make them more consistent (Eliot & Devine, 1994; Harmon-Jones et al., 1996). For example, someone who believes that "smoking is bad" but must also acknowledge that "I smoke" would be motivated to reduce the resulting dissonance. Because it is often difficult to change behavior, people usually reduce cognitive dissonance by changing inconsistent attitudes: Rather than quit smoking, the smoker might decide that smoking is not so bad.

In one of the first studies of cognitive dissonance, Festinger and his colleague Merrill Carlsmith (Festinger & Carlsmith, 1959) asked people to turn pegs in a board, a very dull task. Later, some of these people were asked to persuade a person waiting to participate in the study that the task was "exciting and fun." Some were told that they would be paid \$1 to tell this lie; others were promised \$20. After they had talked to the waiting person, their attitudes toward the dull task were measured.

Figure 17.6 shows the surprising results. The people who were paid just \$1 to lie liked the dull task more than those who were paid \$20. Why? Festinger and Carlsmith (1959) argued that telling another person that a boring task is enjoyable will produce dissonance (between the thoughts "I think the task is boring" and "I am saying it is fun"). To reduce this dissonance, the people who were paid just \$1 adopted a more favorable attitude toward the task, making their cognitions consistent: "I think the task is fun" and "I am saying it is fun." But if a person has adequate justification for the behavior, any dissonance that exists will be reduced simply by thinking about the justification. The participants who were paid \$20 thought they had adequate justification for lying and so did not need to change their attitude toward the task.

Hundreds of other experiments have also found that when people publicly engage in behaviors that are inconsistent with their privately held attitudes, they are

figure 17.6

Cognitive Dissonance and Attitude Change

According to cognitive dissonance theory, people who were paid \$20 to say a boring task was enjoyable had clear justification for lying and should experience little dissonance between what they said and what they thought about the task. In fact, their attitude toward the task did not change much. However, participants who received just \$1 had little justification to lie and reduced their dissonance mainly by displaying a more positive attitude toward the task.

likely to change their attitudes to be consistent with their behavior (Stone & Cooper, 2001). These experiments have also found that behavior-attitude inconsistency will produce attitude change when (1) the inconsistency causes some distress or discomfort in a person and (2) changing attitudes serves to reduce the person's discomfort or distress. But what causes the discomfort? There is considerable debate among attitude researchers about this question (Wood, 2000).

Currently, the most popular of several possible answers is that the discomfort is caused by an inconsistency between people's desire to maintain a positive self-concept and the fact that they have, for example, encouraged another person to do something that they themselves didn't believe in or that they themselves wouldn't do. This inconsistency makes most people feel uncomfortable, and they change their attitudes to reduce or eliminate such feelings (Stone & Cooper, 2001). If people can persuade themselves that they really believed in what they did, the perceived inconsistency disappears, and their positive self-concept is restored. Changing one's private attitude to match one's public actions is one way to accomplish this self-persuasion. Claude Steele's work on *self-affirmation* supports this explanation of why dissonance causes discomfort (e.g., Steele, Spencer, & Lynch, 1993). He has found that people will not change their attitudes after recognizing their own attitude-behavior inconsistency if they can do something else that makes them look good and feel good about themselves (e.g., showing how smart or competent they are). In other words, when people do not need to change their attitudes to reestablish a positive view of themselves, they don't.

The impact of attitude-behavior inconsistencies on attitude change may be greater in individualist cultures of Europe and North America than in collectivist cultures such as Japan and China (e.g., Heine & Lehman, 1997). Where group rather than individual identities are emphasized, behaving at odds with one's personal beliefs may create less discomfort—and thus less motivation for attitude change—because holding to those beliefs tends to be less important for self-esteem.

Self-Perception Theory Over the years, cognitive dissonance theory has been challenged by other explanations of why attitudes change when they are inconsistent with behavior (Dunning, 2001). The first and strongest of these challenges came from Daryl Bem's (1967) **self-perception theory**. Unlike dissonance theory, self-perception theory does not assume that people experience discomfort when their attitudes are inconsistent with their behaviors. According to Bem, situations often arise in which people are not quite sure about their attitudes. When this happens, Bem says, people look at their own behavior under particular circumstances and then infer what their attitude must be. The person says, "If I did that under those circumstances, my attitude must be this." This process makes their attitudes consistent with their behavior, but the process is not driven by tension or discomfort.

Self-perception explanations of attitude change seem reasonable, but two kinds of evidence are inconsistent with it. First, people actually do become physiologically aroused and feel uncomfortable when they experience an inconsistency between their attitudes and behavior, and their discomfort is reduced when they change their attitudes to match their behavior (Elliot & Devine, 1994). This finding suggests that some kind of internal tension is, in fact, created by cognitive dissonance. Second, people adjust their attitudes to match their behavior even when they are unable to reflect on that behavior—a process that is crucial to self-perception theory. In one experiment, for example, researchers studied the effects of attitude-behavior inconsistencies in people suffering from anterograde amnesia, a condition, described in the memory chapter, that leaves its victims unable to recall what they have said or done minutes earlier. Like the participants in other attitude-change experiments, these people, too, changed their attitudes to be more consistent with their behavior (Lieberman et al., 2001).

Although these results do not support self-perception theory, they do not entirely invalidate it. It may be that self-perception theory applies best either when

self-perception theory A theory suggesting that attitudes can change as people consider their behavior in certain situations and then infer what their attitude must be.

in review Forming and Changing Attitudes

Type of Influence	Description
Modeling and conditioning	Attitudes are usually formed through observation of how others behave and speak about an attitude object, as well as through classical and operant conditioning.
Elaboration likelihood model	People change attitudes through either a central or peripheral route, depending on factors such as personal involvement, "cognitive busyness," and personality characteristics.
Cognitive dissonance and self-perception	Inconsistencies between attitudes and behaviors can produce attitude change, as can reviewing one's behavior in light of circumstances.

people have no prior attitude toward some object or when the discrepancy between their attitude and their behavior is slight. For instance, if you know you like Coca-Cola, but you also know that you just drank a Pepsi, this self-perception may drive an attitude change toward Pepsi even though you did not experience any dissonance. However, when attitudes are strong and clearly defined, and the inconsistency between them is larger and more important to one's self-concept, attitude change appears to occur mainly because of cognitive dissonance (Dunning, 2001). ("In Review: Forming and Changing Attitudes" summarizes some of the major processes through which attitudes are formed and changed.)

Biological and Social Psychology

Social psychologists' research on thoughts, feelings, and behaviors was once entirely separate from research on the biological processes that underlie those thoughts, feelings, and behaviors (Winkielman, Berntson, & Cacioppo, 2001). Social psychologists believed that it was not possible to reduce complex social psychological processes to the firing of neurons or the secretion of hormones. For their part, biological psychologists, more commonly known as *neuroscientists*, viewed the study of social psychology as having little, if any, relevance to the understanding of behavioral genetics or the functioning of the nervous, endocrine, or immune systems. Recently, however, scientists in both subfields have begun to take a closer look at each other's research and how their subfields are related. The result has been the emergence of a new specialty called *social neuroscience* or *social cognitive neuroscience* (Cacioppo et al., 2000; Frith & Frith, 2001; Ochsner & Lieberman, 2001). This new specialty focuses on the influence of social processes on biological processes and on the influence of biological processes on social psychological phenomena.

There are many reasons to believe that this approach will be valuable. For example, the chapter on health, stress, and coping contains numerous examples of how social stressors can have health-related biological consequences. Health psychologists have also found that the availability and quality of a person's social support network can affect biological processes ranging from blood pressure to the healing of wounds (Kiecolt-Glaser et al., 1998; Uchino, Cacioppo, & Kiecolt-Glaser, 1996). The social environment can even affect the way genes express themselves. In one study, for example, monkeys were selectively bred to react strongly to even mild stressors. These animals' hypersensitivity appeared to be

LINKAGES (a link to Biological Aspects of Psychology)

based on a specific gene, but researchers found it possible to modify the effects of this gene by changing the monkeys' social situation. When the animals were paired with a warm, nurturant foster mother, their hypersensitivity diminished significantly, and it remained low even when they were later separated from her (Suomi, 1991, 1999).

Researchers are also beginning to identify the biological underpinnings of many social processes. One example of this relationship is seen in studies of how the amygdala is related to the stereotypes and prejudice described in the next section. (As noted in the chapter on motivation and emotion, the amygdala is a brain structure that plays a significant role in emotion.) Using functional magnetic resonance imaging technology, researchers found that European Americans who were prejudiced against African Americans showed significantly more amygdala activity when looking at pictures of black people than when looking at pictures of white people (Hart et al., 2000; Phelps et al., 2000). Social neuroscientists have also used electroencephalography and other techniques to record the brain activity associated with positive and negative attitudes about people and objects. Their research has shown that these evaluative reactions are associated with activity in specific brain regions (Cacioppo, Crites, & Gardner, 1996).

Social cognitive neuroscience is still in its infancy; the first conference devoted to research in this specialty did not occur until April 2001 (Ochsner & Lieberman, 2001). However, that research shows great promise for creating a better understanding of the linkages among social, cognitive, and biological phenomena, as well as a better understanding of complex social and physiological processes.

Prejudice and Stereotypes

All of the principles that underlie impression formation, attribution, and attitudes come together to create prejudice and stereotypes. **Stereotypes** are the perceptions, beliefs, and expectations a person has about members of some group; they are schemas about entire groups of people (Dion, in press). Usually, they involve the false assumption that all members of a group share the same characteristics. Although the characteristics that make up the stereotype may be positive, they are usually negative. The most prevalent and powerful stereotypes focus on observable personal attributes, particularly ethnicity, gender, and age (Operario & Fiske, 2001). As discussed later, people may not be consciously aware of many of the stereotypes they hold (Banaji, Lemm, & Carpenter, 2001).

Stereotyping often leads to **prejudice**, which is a positive or negative attitude toward an individual based simply on his or her membership in some group (Dion, in press). The literal meaning of the word *prejudice* is "prejudgment." Many theorists believe that prejudice, like other attitudes, has cognitive, affective, and behavioral components. Stereotyped thinking is the cognitive component of prejudicial attitudes. The hatred, admiration, anger, and other feelings people have about stereotyped groups constitute the affective component. The behavioral component of prejudice involves **discrimination**, which is differential treatment of individuals who belong to different groups.

stereotypes False assumptions that all members of some group share the same characteristics.

prejudice A positive or negative attitude toward individuals simply because of their membership in a group.

discrimination Differential treatment of individuals who belong to different groups; the behavioral component of prejudice.

Theories of Prejudice and Stereotyping

Prejudice and stereotyping may occur for several reasons (Duckitt, 1994). Let's consider three explanatory theories, each of which has empirical support and accounts for some, but not all, instances of stereotyping and prejudice.

Motivational Theories For some people, prejudice against certain groups might enhance their sense of security and help them meet certain personal needs. This idea was first proposed by T. W. Adorno and his associates fifty years

ago (Adorno et al., 1950); it has since been revised and expanded by Bob Altemeyer (1988, 1996). Specifically, these researchers suggest that prejudice may be especially likely among people who display a personality trait called *authoritarianism*. According to Altemeyer, authoritarianism is composed of three elements: an acceptance of conventional or traditional values, a willingness to unquestioningly follow the orders of authority figures, and an inclination to act aggressively toward individuals or groups identified by these authority figures as threatening the values held by one's in-group. People with an authoritarian orientation tend to view the world as a threatening place (Winter, 1996), and one way to protect themselves from perceived threats is to identify strongly with their in-group and to reject, dislike, and perhaps even punish anyone who is a member of other groups. Looking down on, and discriminating against, out-groups—such as gay men and lesbians, African Americans, or Muslims, for example—may help people with authoritarian tendencies to feel safer, as well as better about themselves (Haddock & Zanna, 1998a).

A more recent motivational explanation of prejudice invokes the concept of social identity discussed earlier. Recall that whether they are authoritarian or not, most people are motivated to identify with their in-group and tend to see it as better than other groups (Brewer & Brown, 1998). As a result, members of an in-group often see all members of out-groups as less attractive and less socially acceptable than in-group members and may thus treat them badly (Jackson, in press). In other words, prejudice may result when people's motivation to enhance their own self-esteem causes them to disrespect other people.

Cognitive Theories Stereotyping and prejudice may also result from the social-cognitive processes people use in dealing with the world. There are so many other people, so many situations in which one meets them, and so many possible behaviors they might perform that one cannot possibly attend to and remember them all. Therefore, people use schemas and other cognitive shortcuts to organize and make sense out of their social world (Fiske, 1998). Often these cognitive processes allow people to draw accurate and useful conclusions about other people, but sometimes they lead to inaccurate stereotypes. For example, one effective way to deal with social complexity is to group people into *social categories*. Rather than remembering every detail about everyone we have ever encountered, we tend to put other people into categories, such as doctor, senior citizen, Republican, student, Italian, and the like (Dovidio, Kawakami, & Gaertner, 2000). To further simplify perception of these categories, we tend to see their members as being quite similar

Schemas and Stereotypes The use of schemas to assign certain people to certain categories can be helpful when deciding who is a customer and who is a store employee, but it can also lead to inaccurate stereotypes. Following the September 11, 2001, terrorist attacks on New York City and Washington, D.C., many people in the United States began to think of all Muslims as potential terrorists, and to discriminate against them. This false assumption, and the problems it created for Muslims in the U.S., was one of the many awful side-effects of the terrorist attacks.

to one another. In fact, members of one ethnic group may find it harder to distinguish among specific faces within other ethnic groups than within their own group (Anthony, Cooper, & Mullen, 1992). People also tend to assume that all members of a different group hold the same beliefs and values and that those beliefs and values differ from their own (Dion, in press). Finally, as noted in the chapter on perception, people's attention tends to be drawn to distinctive stimuli. Noticeably rude behavior by even a few members of an easily identified ethnic group may lead other people to see an *illusory correlation* between rudeness and ethnicity (Hamilton & Sherman, 1994). As a result, they may incorrectly believe that all members of that group are rude.

Learning Theories Some prejudice results from conflicts between members of different groups, but people also develop negative attitudes toward groups with whom they have had little or no contact. Like other attitudes, prejudice can be learned vicariously. Learning theories suggest that children acquire prejudices just by watching and listening to the words and deeds of parents, peers, and others (Rohan & Zanna, 1996). Movies and television may also portray ethnic or other groups in ways that teach stereotypes and prejudice (Smith & Mackie, 2000). One study found, for example, that Hispanics were twice as likely as any other group to be portrayed as criminals in prime-time television shows (Purdue Exponent, 1994). Another study revealed that local news coverage often gives the impression that African Americans are responsible for a higher percentage of crimes than is actually the case (Romer, Jamieson, & de Cocteau, 1998). No wonder so many young children already know about the supposed negative characteristics of certain groups long before they ever meet members of those groups (Mackie et al., 1996; Quintana, 1998).

Reducing Prejudice

One clear implication of the cognitive and learning theories of prejudice and stereotyping is that members of one group are often ignorant or misinformed about the characteristics of people in other groups (Miller & Davidson-Podgorny, 1987). Before 1954, for example, most black and white children in the United States knew very little about one another because they went to separate schools. Then the Supreme Court declared that segregated public schools should be prohibited. By ruling segregation to be unconstitutional, the court created a real-life test of the **contact hypothesis**, which states that stereotypes and prejudice toward a group will diminish as contact with that group increases (Pettigrew & Tropp, 2000).

Did the desegregation of U.S. schools in the 1960s and 1970s confirm the contact hypothesis? In a few schools, integration was followed by a decrease in prejudice, but in most places either no change occurred or prejudice actually increased (Oskamp & Schultz, 1998). However, these results did not necessarily disprove the contact hypothesis. In-depth studies of schools in which desegregation was successful suggested that contact alone was not enough; integration reduced prejudice only when certain social conditions were created (Pettigrew & Tropp, 2000). First, members of the two groups had to be of roughly equal social and economic status. Second, school authorities had to promote cooperation and interdependence between the members of different ethnic groups by having them work together on projects that required reliance on one another to reach success. Third, the contact between group members had to occur on a one-on-one basis; it was only when people got to know one another as individuals that the errors contained in stereotypes became apparent. Finally, the members of each group had to be seen as typical and not unusual in any significant way. When these four conditions prevailed, the children's attitudes toward one another became more positive. These effects are not restricted to schoolchildren in the United States. In Italy, for example, people who had equal-status contact with black immigrants from North Africa displayed less prejudice against them than did Italians who had no contact with the immigrants (Kirchler & Zani, 1995).

contact hypothesis The idea that stereotypes and prejudice toward a group will diminish as contact with the group increases.

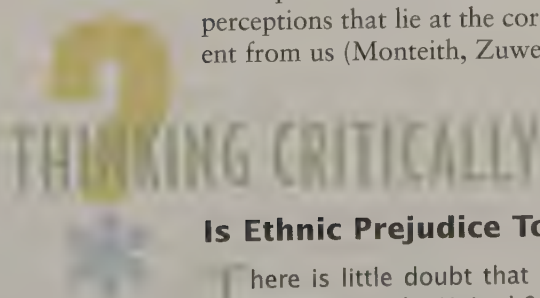

Fighting Ethnic Prejudice Negative attitudes about members of ethnic groups are often based on negative personal experiences or the negative experiences and attitudes people hear about from others. Cooperative contact between equals can help promote mutual respect and reduce ethnic prejudice.

Elliot Aronson (1995) describes a teaching strategy, called the *jigsaw technique*, that helps create the conditions that reduce prejudice. The strategy calls for children from several ethnic groups to work as a team to complete a task, such as writing a report about a famous figure in history. Each child learns, and provides the team with, a separate piece of information about this person, such as place of birth (Aronson, 1990). Studies show that children from various ethnic groups who are exposed to the jigsaw technique and other cooperative learning experiences show substantial reductions in prejudice toward other groups (Aronson, 1997). The success reported in these studies has greatly increased the popularity of cooperative learning exercises in classrooms in the United States. Such exercises may not eliminate all aspects of ethnic prejudice in children, but they seem to be a step in the right direction.

Can friendly, cooperative, interdependent contact reduce the more entrenched forms of prejudice seen in adults? It may. When equal-status adults work jointly toward a common goal, bias and distrust can be reduced. This is especially true if they come to see themselves as members of the same group rather than as belonging to opposing groups (Dovidio, Kawakami, & Gaertner, 2000; Fiske, 2000). The challenge to be met in creating such cooperative experiences in the real world is that the participants must be of equal status—a challenge made more difficult in many countries by the sizable status differences that still exist between ethnic groups (Pettigrew & Tropp, 2000).

In the final analysis, contact provides only part of the solution to the problems of stereotyping, prejudice, and discrimination. To reduce ethnic prejudice, we must develop additional educational techniques that address the social cognitions and perceptions that lie at the core of bigotry and hatred toward people who are different from us (Monteith, Zuwerink, & Devine, 1994).

Is Ethnic Prejudice Too Ingrained Ever to Be Eliminated?

There is little doubt that overt forms of ethnic prejudice have decreased dramatically in the United States over the past thirty to forty years. For example, in the 1950s fewer than half of European American college students surveyed said they were willing to live in integrated neighborhoods; today, about 95 percent say

they would be willing to do so. And three decades ago, fewer than 40 percent of European Americans said they would vote for an African American presidential candidate; over 95 percent now say they might do so (Dovidio & Gaertner, 1998). Despite these welcome changes, research in social psychology suggests that more subtle manifestations of prejudice and discrimination may remain as entrenched in the United States today as they were ten or even fifteen years ago (Dovidio & Gaertner, 2000).

LINKAGES (a link to
Consciousness)

● What am I being asked to believe or accept?

Even people who see themselves as nonprejudiced and who disavow ethnic stereotypes and discrimination still hold negative stereotypes about ethnic out-groups and, in certain situations, will display prejudice and discrimination toward them (Dovidio, Kawakami, & Beach, 2001). Some people claim, therefore, that negative attitudes toward ethnic out-groups are so deeply ingrained in all of us that ethnic prejudice can never be eliminated.

● What evidence is available to support the assertion?

Evidence for this assertion focuses primarily on prejudice against African Americans by European Americans and comes, first, from studies testing the theory of *aversive racism* (Dovidio & Gaertner, 1998). This theory holds that even though many European Americans consider ethnic prejudice to be unacceptable, or aversive, they will still sometimes display it—especially when they can do so without admitting, even to themselves, that they are prejudiced. In one test of this theory, a male experimenter telephoned male and female European Americans who were known to believe in ethnic equality. The man claimed to be a stranded motorist who had misdialed from a pay phone while trying to call a service station for help. When told he had the wrong number, the man replied that he was out of coins and asked the person he'd reached to call a service station for him. If people listened long enough to learn of the man's problem, they were just as likely to contact the service station whether the caller "sounded" European American or African American. However, if the caller "sounded" African American, these supposedly unprejudiced people were almost five times as likely to hang up even before the caller could ask for help (Gaertner & Dovidio, 1986). In other studies, female European American college students were asked to help another female student who was doing poorly on some task. When the student's poor performance was described as being due to the task's difficulty, the students agreed to help, regardless of the other student's ethnicity. But if the problem was said to be due to lack of effort, help was offered much more often to European Americans than to African Americans (Frey & Gaertner, 1986; McPhail & Penner, 1995). These findings suggest that even people who do not display prejudice in most situations may do so in others.

LINKAGES (a link to
Consciousness)

A second line of evidence for the entrenchment of prejudice comes from research showing that many people hold negative stereotypes about ethnic minorities (and women) but are unaware that they do so. These negative stereotypes can also be *activated* without conscious awareness, even among people who believe they are free of prejudice (Banaji, Lemm, & Carpenter, 2001; Wheeler & Petty, 2001). To demonstrate these phenomena, researchers have used the priming procedures described in the chapter on consciousness to activate unconscious thoughts and feelings that can alter people's reactions to stimuli without their awareness. In one study, for example, white participants were exposed to subliminal presentations of pictures of black individuals (Chen & Bargh, 1997). The participants were not consciously aware that they had seen these pictures, but when they interacted with a black man soon thereafter, those who had been primed with the pictures acted more negatively toward him and saw him as more hostile than did people who had not been primed. Priming apparently activated these participants' negative ethnic stereotypes. It is also possible to prime unconscious negative stereotypes about other groups, including women and the elderly (Glick &

LINKAGES (a link to Perception)

Fiske, 2001; Hense, Penner, & Nelson, 1996). All of these findings suggest that stereotypes are so well learned and so ingrained in people that they may be activated automatically and without their conscious awareness (Dovidio, Kawakami, & Beach, 2001).

● **Are there alternative ways of interpreting the evidence?**

The evidence presented so far suggests that it may be impossible to eliminate ethnic prejudice, because everyone harbors unconscious negative stereotypes about various groups. But this evidence does not necessarily mean that unconscious stereotypes affect everyone in the same way. Perhaps they have a greater impact on people who are more overtly prejudiced.

● **What additional evidence would help to evaluate the alternatives?**

One way to evaluate this possibility is to compare the responses of prejudiced and nonprejudiced people in various experimental situations. In one mock-trial study, for example, overtly prejudiced white jurors recommended the death penalty more often for black defendants than for white defendants found guilty of the same crime, but low-prejudice white jurors showed this bias only when they believed that a black member of the jury also favored giving the death penalty (Dovidio et al., 1997). Priming studies, too, show that although negative stereotypes can be primed in both prejudiced and nonprejudiced people, it is easier to do in people who openly display their ethnic bias (Dovidio, Kawakami, & Gaertner, 2000). Furthermore, activation of these stereotypes may be less likely to affect the conscious attitudes and behavior of nonprejudiced people. So when unconscious stereotypes are activated in nonprejudiced people, the effects tend to appear in subtle ways, such as in facial expressions or other nonverbal behaviors (Kawakami, Dion, & Dovidio, 1998; Lepore & Brown, 1997).

● **What conclusions are most reasonable?**

Taken together, research evidence presents a mixed picture regarding the possibility of eliminating ethnic prejudice. True, people in the United States are not nearly as colorblind as we might hope, and ethnic prejudice may be so ingrained in some people as to be subconscious. However, recent research suggests that it may still be possible to eliminate even subconscious stereotypes (Kawakami et al., 2000; Kurzban, Tooby, & Cosmides, 2001). It also appears that when nonprejudiced people are made aware of their negative beliefs about some target group, they will actively work to prevent those beliefs from influencing their behavior toward members of that group (Devine, Plant, & Buswell, 2000). In short, prejudice is ingrained, but it can also be reduced, and it makes sense to do everything possible to reduce it. In the United States, as in any multicultural country, survival as a civilized society requires that we all continue to fight against overt and covert forms of stereotyping, prejudice, and discrimination. This goal is more important than ever, as fear of, and the fight against, international terrorism can make it all too easy to misjudge and mistreat innocent people based on their ethnicity.

Interpersonal Attraction

Research on prejudice helps illuminate some of the reasons for which people, from childhood on, may come to dislike or even hate other people. An equally fascinating aspect of social cognition is why people like or love other people. Folklore tells us that “opposites attract,” but it also maintains that “birds of a feather flock together.” Although valid to some degree, each of these statements needs to be qualified in important ways. We begin our coverage of interpersonal attraction by discussing the factors that lead to initial attraction; we then examine how liking sometimes develops into more intimate relationships.

TRY THIS

Proximity and Liking

Research on environmental factors in attraction suggests that barring bad first impressions, the more often we make contact with someone—as neighbors, classmates, or co-workers, for example—the more we tend to like that person. Does this principle apply in your life? To find out, think about how and where you met each of your closest friends. If you can think of cases in which proximity did not lead to liking, what do you think interfered with the formation of friendship?

Keys to Attraction

Whether you like someone or not depends partly on situational factors and partly on personal characteristics.

The Environment

One of the most important determinants of attraction is simple physical proximity (Berscheid & Reis, 1998). As long as you do not initially dislike a person, your liking for that person will increase with additional contact (Bornstein, 1992). For example, Richard Moreland and Scott Beach (1992) varied the number of times that several experimental assistants (posing as students) attended a class. Even though none of the assistants spoke to anyone in the class, they were rated by the other students as more likable the more often they attended. A more recent study found that such ratings generalized to individuals who resembled the people who had been present (Rhodes, Halberstadt, & Brajkovich, 2001). This proximity phenomenon—another example of the *mere-exposure effect* mentioned earlier—helps account for why next-door neighbors are usually more likely to become friends than people who live farther from one another. Chances are, most of your friends are people whom you met as neighbors, co-workers, or classmates.

The circumstances under which people first meet also influence attraction. In accordance with the conditioning principles discussed in the chapter on learning, you are much more likely to be attracted to a stranger if you meet in comfortable, rather than uncomfortable, physical conditions. Similarly, if you are rewarded in the presence of a stranger, the chances that you will like that stranger are increased, even if the stranger was not the one who gave the reward (Clark & Pataki, 1995). In one study, for example, an experimenter judged one person's creativity while another person watched. Compared with those who received a negative evaluation, participants who were evaluated positively tended to like the observer more (Griffitt & Guay, 1969). At least among strangers, then, liking can occur through associating someone with something pleasant.

Similarity

People also tend to like those they perceive as similar to themselves on variables such as age, religion, smoking or drinking habits, or being a “morning” or “evening” person. As shown in Figure 17.7, similarity in attitudes is an especially important influence on attraction. This relationship has been found among children, college students, adult workers, and senior citizens (Brehm, Kassins, & Fein, 2002).

Similarity in attitudes toward mutual acquaintances is a particularly good predictor of liking, because in general, people prefer relationships that are *balanced*. As illustrated in Figure 17.8, if Zoe likes Abigail, the relationship is balanced as long as they agree on their evaluation of a third person, Samantha, regardless of whether they like or dislike that third person. However, the relationship will be imbalanced if Zoe and Abigail disagree on their evaluation of the third person.

One reason why we like people with similar views of the world is that we expect such people to think highly of us (Condon & Crano, 1988). Like many important relationships, it's hard to say whether attraction is a cause or an effect of similarity (Berscheid & Reis, 1998). For example, you might like someone because his attitudes are similar to yours, but it is also possible that as a result of liking him, your attitudes will become more similar to his (Davis & Rusbult, 2001). Even if your own attitudes do not change, you may change your *perceptions* of the liked person's attitudes such that those attitudes seem more similar to yours (Brehm, 1992).

Physical Attractiveness

Physical characteristics are another important factor in attraction, particularly during the initial stages of a relationship (Berscheid & Reis, 1998). From preschool through adulthood, physical attractiveness is a key to popularity with members of both sexes (Aronson, Wilson, & Akert, 2002; Lemly,

figure 17.7

Attitude Similarity and Attraction

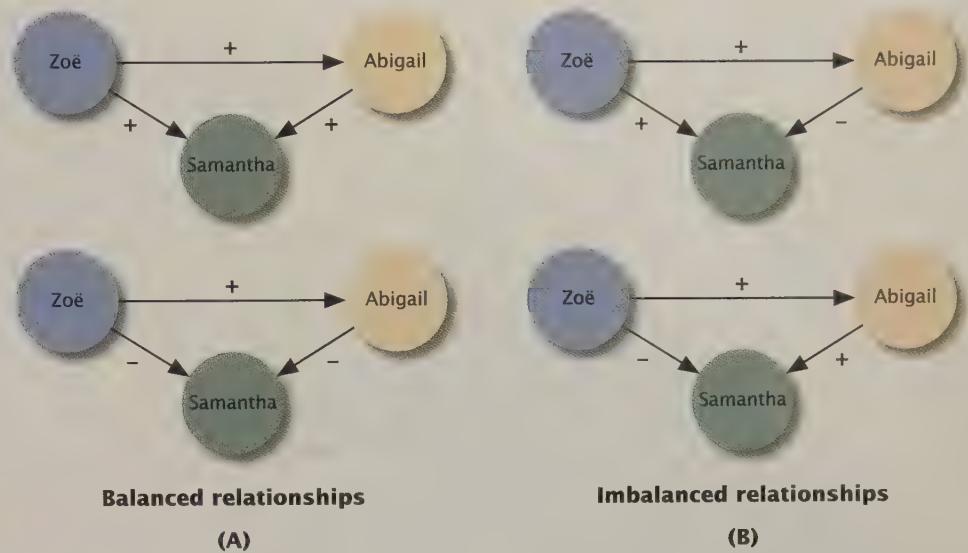

This graph shows the results of a study in which participants learned about another person's attitudes. Their liking for that person was strongly related to the proportion of his or her attitudes that were similar to the participants' own.

figure 17.8

Balanced and Imbalanced Relationships

Here are some common examples of balanced and imbalanced patterns of relationships among three people. The plus and minus signs refer to liking and disliking, respectively. Balanced relationships are comfortable and harmonious; imbalanced ones often bring conflict.

2000). Consistent with the **matching hypothesis** of interpersonal attraction, however, people tend to date, marry, or form other committed relationships with those who are similar to themselves in physical attractiveness (Yela & Sangrador, 2001). One possible reason for this outcome is that people tend to be most attracted to those with the greatest physical appeal, but they also want to avoid rejection by such individuals. In short, it may be compromise, not preference, that leads people to pair off with those who are roughly equivalent to themselves in physical attractiveness (Carli, Ganley, & Pierce-Otay, 1991).

Intimate Relationships and Love

There is much about intimate relationships that psychologists do not—and may never—understand, but they are learning all the time. As mentioned in the chapter on motivation and emotion, evolutionary psychologists suggest that men and women employ different strategies to ensure the survival of their genes, and that each gender looks for different attributes in a potential mate (Buss, 1999; Buss & Kenrick, 1998; Kenrick, Neuberg, & Cialdini, 2002). For example, women may be much more concerned than men about the intelligence level of their dating partners (Kenrick & Trost, 1997; see Figure 17.9).

Intimate Relationships Eventually, people who are attracted to each other usually become *interdependent*, which means that the thoughts, emotions, and behaviors of one person affect the thoughts, emotions, and behaviors of the other (Rusbult, Arriaga, & Agnew, 2001). Interdependence is one of the defining characteristics of intimate relationships. It occurs in large measure as the thoughts and values of one person become part of the self-concept of the other (Agnew et al., 1998).

Another key component of successful intimate relationships is *commitment* to the relationship, which is the extent to which each party is psychologically attached to the relationship and wants to remain in it (Rusbult & Van Lange, 1996). People feel committed to a relationship when they are satisfied with the rewards they receive from it, when they have invested considerable resources (both tangible and intangible) in it, and when there are few attractive alternative relationships available to them (Bui, Peplau, & Hill, 1996).

matching hypothesis The notion that people are most likely to form long-term relationships with those who are similar to themselves in physical attractiveness.

Analyzing Love Affection, emotional expressiveness, social support, cohesiveness, and sexuality—these characteristics of intimate relationships are likely to

figure 17.9

Sex Differences in Date and Mate Preferences

According to evolutionary psychologists, men and women have developed different strategies for selecting sexual partners. They say that women became more selective than men because they can have relatively few children and want a partner who has the ability to help care for those children. Here are some data supporting this idea. When asked about the intelligence of people they would choose for one-night stands, dating, and sexual relationships, women preferred much smarter partners than men did. Only when the choices concerned steady dating and marriage did the men's preference for bright partners equal that of the women. Critics of the evolutionary approach explain such sex differences as reflecting learned social norms and expectations of how men and women should behave (Eagly & Wood, 1999).

Source: Kenrick et al. (1993).

bring something else to mind: love. Yet *intimacy* and *love* are not synonymous. Most theorists agree that there are several different types of love (Brehm, Kassin, & Fein, 2002). One widely accepted view distinguishes between *passionate love* and *companionate love* (Hatfield & Rapson, 1995). Passionate love is intense, arousing, and marked by both strong physical attraction and deep emotional attachment. Sexual feelings are very strong, and thoughts of the other intrude on a person's awareness frequently. Companionate love is less arousing but psychologically more intimate. It is marked by mutual concern for the welfare of the other (Hendrick & Hendrick, 1986).

Robert Sternberg (1988a) has offered a more comprehensive analysis of love. According to his *triangular theory*, the three basic components of love are *passion*,

A Wedding in India Most people in Western cultures tend to marry a person they choose on the basis of love, sometimes without regard for discrepancies in religion, ethnicity, and financial or social status. In other cultures, however, these sociocultural considerations—and even arrangements made by parents—may largely determine who marries whom. What factors do you think might have brought this couple together?

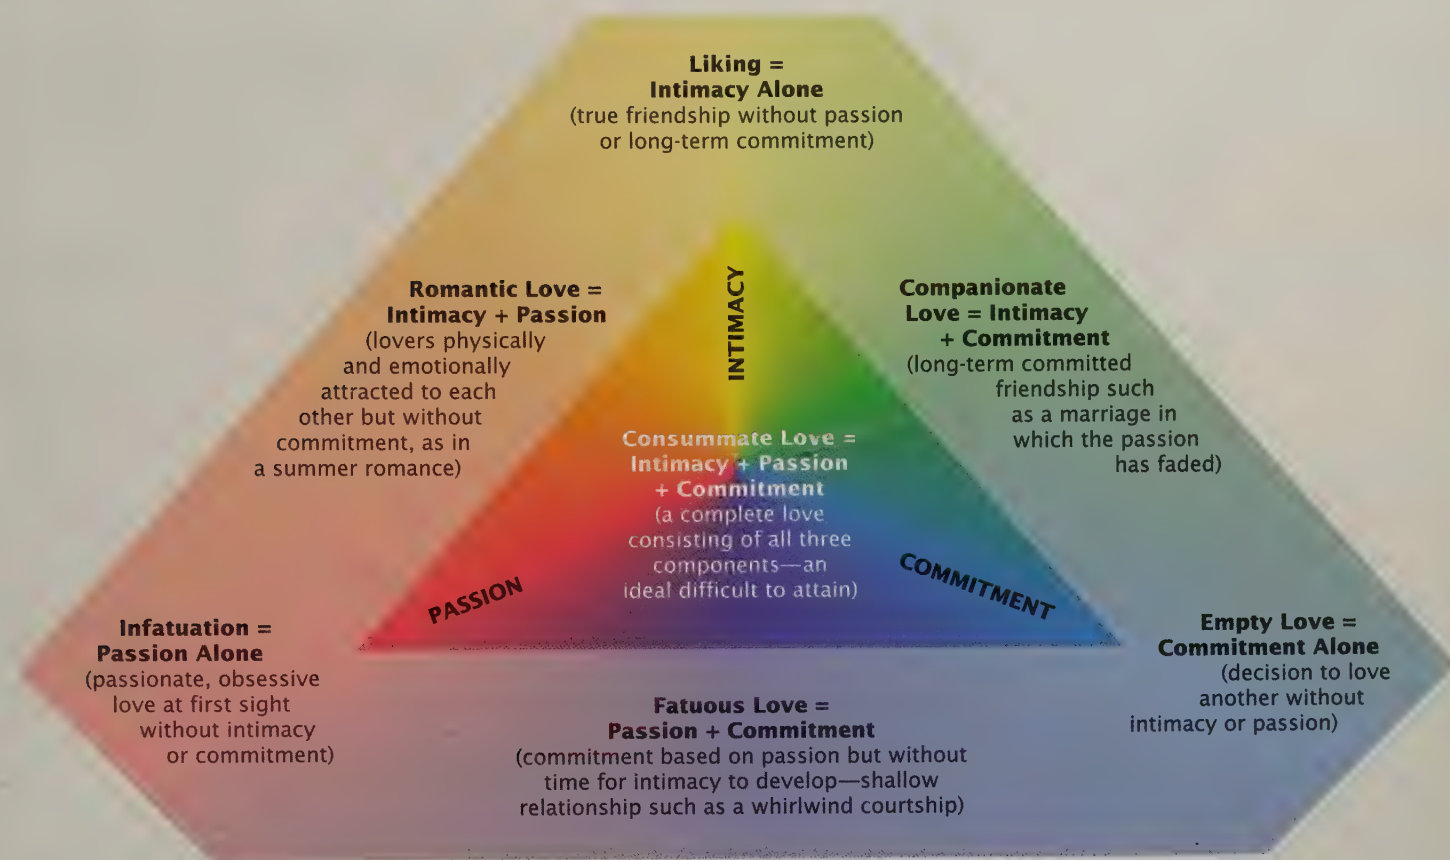

figure 17.10

A Triangular Theory of Love

According to Sternberg, different types of love result when the three basic components proposed in his triangular theory occur in different combinations. Sternberg has also begun to explore factors associated with falling in love (Sternberg, 2000; Sternberg, Hojjat, & Barnes, 2001). Preliminary results suggest that people who share similar views about what a loving relationship should be like are much more likely to fall in love with each other, and to remain committed to the relationship, than are people whose views on love are dissimilar.

Source: "Triangulating Love." In R. J. Sternberg & M. L. Barnes, *The Psychology of Love*. New Haven: Yale University Press. (pp. 500, 520)

intimacy, and *commitment*. Various combinations of these components result in quite different types of love, as illustrated in Figure 17.10. For example, Sternberg suggests that *romantic love* involves a high degree of passion and intimacy, yet lacks substantial commitment to the other person. *Companionate love* is marked by a great deal of intimacy and commitment but little passion. *Consummate love* is the most complete and satisfying. It is the most complete because it includes a high level of all three components, and it is the most satisfying because the relationship is likely to fulfill many of the needs of each partner.

Cultural factors have a strong influence on the value that people place on love. In North America and the United Kingdom, for example, the vast majority of people believe that they must love the person they marry. By contrast, in India and Pakistan, about half the people interviewed in a survey said they would marry someone they did not love if that person had other qualities that they desired (Levine et al., 1995). In Russia, only 40 percent of the people say that they married for love; rather, most married because of loneliness, shared interests, or an unplanned pregnancy (Baron & Byrne, 1994).

Strong and Weak Marriages Long-term studies of successful and unsuccessful marriages suggest that premarital attitudes and feelings are predictive of

TRY THIS

Happy and Healthy People in satisfying marriages and other long-term relationships tend to enjoy better physical and psychological health than those in unsatisfying relationships. In light of research described in the chapter on health, stress, and coping, make a list of reasons why this might be the case.

marital success. For example, one study found that couples who had a close, intimate relationship and similar attitudes when they were dating were more likely to still be married fifteen years later (Hill & Peplau, 1998). Also, still-married couples were more likely to have had a premarital relationship that was rewarding and balanced.

Among married couples, women—but not men—generally tend to be more satisfied with their marriage when the partners talk a lot about the relationship (Acitelli, 1992). Partners in successful marriages also tend to share each other's view of themselves and the other, even if that view is a negative one (Swann, De La Ronde, & Hixon, 1994). The perception that the relationship is fair or equitable also enhances marital satisfaction (Grote & Clark, 2001). After the birth of a first child, for example, many wives find that they have much more work than they had anticipated. If their husbands do not share this work to the degree they expected, wives' marital satisfaction tends to decrease (Hackel & Ruble, 1992).

Long-term studies of marriage have helped researchers identify some of the factors leading to divorce. Two of these factors, frequent conflicts and negative feelings toward one another, are especially associated with divorces that occur shortly after marriage. In these couples, the husband and wife trade increasingly nasty and hurtful remarks until communication breaks down (Gottman et al., 1998). A different picture emerges, however, in couples whose divorce occurs only after many years of marriage. These people do not necessarily display more negative emotions toward one another than couples who stay married, but they are less likely to express positive feelings and love toward one another. In other words, these later-divorcing couples may not dislike one another; they just don't love one another (Gottman & Levenson, 2000; Huston et al., 2001). These findings can help us understand why people in an apparently strong marriage suddenly announce that they are divorcing, and why they may remain friends afterward.

LINKAGES

As noted in the chapter on introducing psychology, all of psychology's subfields are related to one another. Our discussion of brain activity and attitudes illustrates just one way in which the topic of this chapter, social cognition, is linked to the subfield of biological psychology (see the chapter on biological aspects of psychology). The Linkages diagram shows ties to two other subfields as well, and there are many more ties throughout the book. Looking for linkages among subfields will help you see how they all fit together and help you better appreciate the big picture that is psychology.

SUMMARY

Social cognition (the mental processes through which people perceive and react to others) is one aspect of *social psychology* (the study of how people influence, and are influenced by, other people).

Social Influences on the Self

People's social and cultural environments affect their thoughts and feelings about themselves, including their *self-esteem* and their *self-concept*.

Social Comparison

When people have no objective criteria by which to judge themselves, they engage in *social comparison* (using others) or *temporal comparison* (using themselves at an earlier time) as their standard. Such comparison can affect self-evaluation, or self-esteem. Categories of people that are habitually used for social comparison are known as *reference groups*. Comparison to reference groups sometimes produces *relative deprivation*, which in turn can cause personal and social turmoil.

Social Identity Theory

A person's *social identity* is formed from beliefs about the groups to which the person belongs. Social identity affects the beliefs we hold about ourselves. It permits people to feel part of a larger group, engendering loyalty and sacrifice from group members but also potentially creating bias and discrimination toward people who are not members of the group.

Self-Schemas

Through social comparison and the formation of social identity, people develop mental representations of their views and beliefs about themselves. These mental representations, called *self-*

schemas, are part of one's self-concept. Self-schemas can affect people's emotional reactions to events.

Social Perception

Social perception concerns the processes by which people interpret information about others, form impressions of them, and draw conclusions about the reasons for their behavior.

The Role of Schemas

Schemas, the mental representations about people and social situations that we carry into social interactions, affect what we pay attention to, what we remember, and how we judge people and events.

First Impressions

First impressions are formed easily and quickly, in part because people apply existing schemas to their perceptions of others. First impressions change slowly because people are "cognitive misers"; once we form an impression about another person, we try to maintain it. Schemas, however, can create *self-fulfilling prophecies*, leading people to act in ways that bring out in others behavior that is consistent with expectations.

Explaining Behavior: Attribution

Attribution is the process of explaining the causes of people's behavior, including one's own. Observers tend to attribute behavior to causes that are either internal or external to the actor. In general, they do this by looking at three aspects of the behavior: consensus, consistency, and distinctiveness. People from different cultures may sometimes reach different conclusions about the causes of an actor's behavior.

Biases in Attribution

Attributions are affected by biases that systematically distort one's view of behavior. The most common attributional biases are the *fundamental attribution error* (and its cousin, the ultimate attribution error), the *actor-observer bias*, and the *self-serving bias*. Personal and cultural factors can affect the extent to which people exhibit attributional biases.

The Self-Protective Functions of Social Cognition

People often protect themselves from admitting something threatening about themselves through unrealistic optimism and a feeling of unique invulnerability.

Attitudes

An *attitude* is the tendency to respond positively or negatively to a particular object. Attitudes affect a wide range of behaviors.

The Structure of Attitudes

Many theorists believe that attitudes have three components: the cognitive (beliefs), affective (feelings), and behavioral (actions) components. However, it is often difficult to predict a specific behavior from a person's beliefs or feelings about an object. Cognitive theories propose that attitudes consist of evaluations of an object that are stored in memory. This approach suggests that the likelihood of attitude-behavior consistency depends on the accessibility of evaluations in memory, on subjective norms, on perceived control over the behavior, and on prior direct experience with the attitude object.

Forming Attitudes

Attitudes can be learned through modeling, as well as through classical or operant conditioning. They are also subject to the mere-exposure effect: All else being equal, people develop greater liking for a new object the more often they are exposed to it.

Changing Attitudes

The effectiveness of a persuasive message in changing attitudes is influenced by the characteristics of the person who communicates it, by its content, and by the audience receiving it. The *elaboration likelihood model* suggests that attitude change can occur via either the peripheral or the central route, depending on a person's ability and motivation to carefully consider an argument. Another approach to attitude change is to change a person's behavior in the hope that the person's attitude will be adjusted to match the behavior. *Cognitive dissonance theory* holds that if inconsistency between attitudes and behavior creates discomfort related to a person's self-concept or self-image, the person will be motivated to reduce that discomfort. *Self-perception theory* suggests that such attitude changes occur in some cases as people look to their behavior for clues about what their attitudes are.

Prejudice and Stereotypes

Stereotypes often lead to *prejudice* and *discrimination*.

Theories of Prejudice and Stereotyping

Motivational theories of prejudice suggest that some people have a need to disrespect and dislike others. This need may stem from the trait of authoritarianism, as well as from a strong social identity. In either case, feeling superior to members of out-groups helps these people to feel better about themselves. As a result, in-group members tend to discriminate against out-groups. Cognitive theories suggest that people categorize others into groups in order to reduce social complexity. And learning theories maintain that stereotypes, prejudice, and discriminatory behaviors can be learned from parents, peers, and the media.

Reducing Prejudice

The *contact hypothesis* proposes that intergroup contact can reduce prejudice and lead to more favorable attitudes toward a stereotyped group—but only if the contact occurs under specific conditions, such as when there is equal status between group members. Helping diverse people to feel as if they belong to the same group can also reduce intergroup prejudice.

Interpersonal Attraction

Keys to Attraction

Interpersonal attraction is a function of many variables. Physical proximity is important because it allows people to meet. The situation in which they meet is important because positive or negative aspects of the situation tend to be associated with the other person. Characteristics of the other person are also important. Attraction tends to be greater when two people share similar attitudes and characteristics. Physical appearance plays a role in attraction; initially, attraction is strongest to those who are most physically attractive. But for long-term relationships, the *matching hypothesis* applies: People tend to choose others whose physical attractiveness is about the same as theirs.

Intimate Relationships and Love

A defining characteristic of intimate relationships is interdependence, and a key component of successful relationships is commitment. Commitment, in turn, is affected by the rewards coming from the relationship, by the resources invested in it, and by the possible alternatives open to each party. Robert Sternberg's triangular theory suggests that love is a function of three components: passion, intimacy, and commitment. Varying combinations of these three components create different types of love. Couples who have long and successful marriages are likely to perceive the relationship as fair to both parties, and they are likely to share warm and loving feelings for each other.

Summary

In the days following the September 11, 2001, attacks on the World Trade Center and the Pentagon—and also after anthrax bacteria were mailed to news organizations and the U.S. Congress—cities throughout the United States experienced a substantial increase in false bomb threats, anthrax hoaxes, and other “copycat” crimes apparently inspired by the terrorists’ actions. Unfortunately, this phenomenon is not unusual. After the murderous rampage at Columbine High School, for example, a number of students at other high schools were arrested for threatening similar acts of violence against their classmates. Well-publicized suicides, too, are often copied (Garland & Zigler, 1993; Phillips & Cartensen, 1986); after German television reported the case of a young man who killed himself by jumping in front of a train, there was a dramatic increase in railway suicides (Schmidtke & Hafner, 1988). Even telecasts of major professional boxing matches are typically followed by a small increase in murders.

Do these correlations mean that media coverage of violence triggers similar violence? As described in the chapter on learning, televised violence can play a causal role in aggressive behavior, but there are additional reasons to believe that when suicides and murders become media events, they stimulate people to imitate them. For one thing, many of the people who kill themselves soon after a notable suicide bear a strong similarity to the original victim (Cialdini, 2001). The copycat railway suicides in Germany, for example, were committed almost exclusively by other young German men. Further, murder victims in the days following a professional championship fight are more likely to be young white men if the losing boxer was white, and more likely to be young black men if the loser was black (Miller et al., 1991).

Copycat, or imitative, crimes illustrate the effects of *social influence*, the process whereby the words or actions of other people directly or indirectly influence a person’s behavior. This chapter begins with a discussion of social influence itself, after which we consider several related aspects of how we are influenced by others, including the processes of conformity, compliance, and obedience. Then we explore the causes and consequences of aggression and altruism. Finally, we examine several different circumstances in which people jointly influence one another’s behavior, especially circumstances in which people compete with one another for some scarce resource or work together in groups to solve some problem.

Social Influence

Copycat crimes are but one example of the fact that people can influence the way other people think, feel, and act, even without specifically trying to do so (Cialdini, 2001). The most pervasive, yet subtle, form of social influence is communicated through social norms.

Norms are learned, socially based rules that prescribe what people should or should not do in various situations (Cialdini & Trost, 1998). Norms are transmitted by parents, teachers, clergy, peers, and other agents of culture. Although they often cannot be verbalized, norms are so powerful that people usually follow them automatically. At movie theaters in North America, for example, norms tell us that we should get in line to buy a ticket rather than crowd around the ticket window; they also lead us to expect that others will do the same. By informing people of what is expected of them and others, norms make social situations less uncertain and more comfortable.

Robert Cialdini and his associates (1990) have described social norms as either descriptive or injunctive. *Descriptive norms* indicate how most other people actually behave in a given situation. They tell a person what actions are common in the situation and thereby implicitly give the person permission to act in the same way. The fact that most people do not cross a street until the green light or “walk” sign appears is an example of a descriptive norm. *Injunctive norms* give more specific information about the actions that others find acceptable and those that they find

norms Socially based rules that prescribe what people should or should not do in various situations.

figure 18.1

Descriptive and Injunctive Norms

A descriptive norm, communicated by the littering of a messy parking lot, led many observers to litter, too. A clean lot changed the descriptive norm, leading fewer observers to imitate a litterer. An injunctive norm (communicated by the picking up of litter) was not altered significantly by the condition of the lot (Reno, Cialdini, & Kallgren, 1993). Research like this is being applied to combat alcohol abuse on college campuses. Rather than focusing on the dangers of alcohol, some student health campaigns create a descriptive norm for responsible drinking by citing statistics showing that most students drink in moderation (Zernike, 2000).

Source: Adapted from Reno, Cialdini, & Kallgren (1993).

unacceptable. Subtle pressure exists to behave in accordance with these norms. A sign that reads, “Do not cross on red” or the person next to you saying the same thing is an example of an injunctive norm.

A study by Raymond Reno and his colleagues (Reno, Cialdini, & Kallgren, 1993) illustrates the differing effects of these two types of norms. The participants were people who walked through a parking lot just after being handed an advertising leaflet. The experimenters arranged for the participants to see another person (who was working with the experimenters) either toss a paper bag on the ground or pick one up from the ground. On half the trials of this experiment, the parking lot was littered with paper; on the other half, the lot was clean. As shown in Figure 18.1, the descriptive norm—seeing another person litter in an already dirty environment—appeared to communicate that “many people do this,” and a relatively high percentage of people dropped their own leaflet in the dirty parking lot. By contrast, the injunctive norm—seeing someone pick up litter—appeared to communicate that even though many people litter, one should not do so. When this norm was evident, fewer than 5 percent of the people dropped their leaflet in the dirty parking lot.

One very powerful injunctive norm is *reciprocity*, the tendency to respond to others as they have acted toward you (Cialdini & Trost, 1998). So when a researcher sent Christmas cards to strangers, most responded with a card of their own; some even added a personal note of good cheer (Kunz & Woolcott, 1976). But norms are not universal (Miller, 2001), as illustrated by the fact that people around the world differ greatly in terms of the physical distance they maintain between themselves and others while interacting. For example, people from South America usually stand much closer to one another than do people from North America. And as suggested in the chapter on psychological disorders, behavior considered normal and friendly in one culture may be seen as abnormal, and even offensive, in another.

The social influence exerted by norms creates orderly social behavior. But social influence can also lead to a breakdown in order. For example, *deindividuation* is a psychological state in which a person becomes “submerged in a group” and loses the sense of individuality (Prentice-Dunn & Rogers, 1989). When people experience deindividuation, they undergo heightened emotional arousal and intense feelings of cohesiveness with the group; they appear to become part of the “herd,” and they may do things that they would not do otherwise. Deindividuation appears to be caused by two factors. The first is the belief that one cannot be held personally

deindividuation A psychological state occurring in group members that results in loss of individuality and a tendency to do things not normally done when alone.

Clothing and Culture The social norms that guide how people dress and behave in various situations are part of the culturally determined socialization process described in the chapter on human development. The process is the same worldwide—parents, teachers, peers, religious leaders, and others communicate their culture’s social norms to children—but differences in those norms result in quite different behaviors from culture to culture.

Deindividuation Robes, hoods, and group rituals help create deindividuation in these Ku Klux Klansmen by focusing their attention on membership in their organization and on its values. The hoods also hide their identities, thus reducing their sense of personal responsibility and accountability and making it easier for them to engage in hate crimes and other cowardly acts of bigotry. Deindividuation operates in other groups, too, ranging from lynch mobs and terrorist death squads to political protesters and urban rioters. In short, people who feel themselves to be anonymous members of a group may engage in antisocial acts that they might not perform on their own.

accountable for one's actions. The second is a shifting of attention away from internal thoughts and standards and toward the external environment (Smith & Mackie, 2000). This shift of attention can be intensified when members of the group act in unison, such as by singing together or wearing uniforms (Ku Klux Klan robes, for example).

Deindividuation often results in antisocial acts, and the emotional arousal that it generates makes such behavior difficult to stop (Aronson, Wilson, & Akert, 2002). The greater the sense of anonymity, the more extreme the behavior. An analysis of newspaper accounts of lynchings in the United States over a fifty-year period showed that larger lynch mobs were more savage and vicious than smaller ones (Mullen, 1986). Deindividuation provides an example of how, given the right circumstances, quite normal people can engage in destructive, even violent, behavior.

LINKAGES (a link to Motivation and Emotion)

Motivation and the Presence of Others

In the chapter on motivation and emotion, we noted that social factors such as parental attitudes toward achievement often affect motivation. But a person's current motivational state is also affected by the mere presence of other people. As an illustration, consider what was probably the first experiment in social psychology, conducted by Norman Triplett in 1897.

Triplett noticed that bicycle racers tended to go faster when other racers were nearby than when they were alone. Did seeing one another remind the racers of the need to go faster to win? To test this possibility, Triplett arranged for bicyclists to complete a twenty-five-mile course under three conditions: riding alone in a race against the clock; riding with another cyclist, but not in competition; or competing directly with another rider. The cyclists went much faster when another rider was present than when they were simply racing against time. This was true even when they were not competing against the other person. Something about the presence of the other person, not just competition, produced increased speed.

The term **social facilitation** describes circumstances in which the mere presence of other people can improve performance (Aiello & Douthitt, 2001). This improvement does not always occur, however. The presence of other people sometimes hurts performance, a process known as **social impairment**. For decades

social facilitation A phenomenon in which the presence of others improves a person's performance.

social impairment A reduction in performance due to the presence of other people.

Social Facilitation On his way to a new home run record during the 2001 baseball season, Barry Bonds, shown here adding to his total, was able to perform at his best even though large crowds were present. In fact, the crowds probably helped him hit well, because the presence of others tends to increase arousal, which enhances the performance of familiar and well-learned skills, such as a batting swing. However, arousal created by an audience tends to interfere with the performance of unfamiliar and poorly developed skills. This is one reason why professional athletes who show flawless grace in front of thousands of fans are likely to freeze up or blow their lines in front of a small production crew when trying for the first time to tape a TV ad or a public service announcement.

these results seemed contradictory; then Robert Zajonc (pronounced “ZYE-onze”) suggested that both effects could be explained by one process: arousal.

The presence of other people, said Zajonc, increases a person’s general level of arousal or motivation (Zajonc, 1965). Why? One reason is that being watched by others increases our sense of being evaluated, producing apprehension that in turn increases emotional arousal (Penner & Craiger, 1992). Arousal increases the tendency to perform those behaviors that are most *dominant*—the ones we know best—and this tendency can either help or hinder performance. If you are performing an easy, familiar task, such as riding a bike, the increased arousal caused by the presence of others should allow you to ride even faster than normal. But if the task is hard or unfamiliar—such as trying new dance steps or playing a piano piece you just learned—the most dominant responses may be incorrect and cause your performance to suffer. In other words, the impact of other people on performance depends on whether the task is easy or difficult. Research shows that this is true even when the “other person” is a machine that records one’s errors at a task (Aiello & Kolb, 1995).

The presence of others may affect performance in other ways as well. For example, having an audience may distract us from the task at hand or cause us to focus on only one part of it, thus impairing performance (Aiello & Douthitt, 2001).

What if a person is not merely in the presence of others but is actually working on a task with them? Research indicates that the impact of their presence changes slightly under these conditions (Sanna, 1992). In these situations, people typically exert less effort than they do when performing alone, a phenomenon termed **social loafing** (Karau & Williams, 1997). Whether the task is pulling on a rope, clapping as loudly as possible, or trying to solve intellectual puzzles, people tend to work harder when performing alone than with others (Baron, Kerr, & Miller, 1992; Geen, 1991). There are at least three reasons behind this social loafing phenomenon. First, it is usually much harder to evaluate the performance of individuals when they are working as part of a group (Szymanski, Garczynski, & Harkins, 2000). As a result, it is simply easier to “get away” with loafing when in a group. Second, rewards may come to a group whether or not every member exerts maximum effort. Third, a group’s rewards are usually divided equally among its members rather than according to individual effort (Karau & Williams, 1997).

In North American and other Western countries, social loafing can be seen in groups of all sorts, from volunteer committees to search parties. Because social loafing can reduce productivity in business situations, it is important for managers to develop ways of evaluating the efforts of every individual in a work group, not

social loafing Exerting less effort when performing a group task than when performing the same task alone.

just the overall output of the team (Shepperd, 1993). Social loafing can also be reduced by strategies that cause people to like the group and identify with it (Karau & Williams, 1997).

Social loafing is much less common in Eastern cultures, such as those of China and Japan. In fact, in collectivist cultures, working in a group usually produces *social striving*—defined as greater individual effort when working in a group (Matsumoto, 2000). This difference in the effects of group membership on individual efforts probably reflects the value that collectivist cultures place on coordinated and cooperative group activities. This orientation serves to discourage social loafing.

Conformity and Compliance

Suppose you are with three friends. One says that Franklin Roosevelt was the greatest president in the history of the United States. You think that the greatest president was Abraham Lincoln, but before you can say anything, another friend agrees that it was Roosevelt, and then the other one does as well. What would you do? Disagree with all three? Maintain your opinion but keep quiet? Change your mind?

When people change their behavior or beliefs to match those of other members of a group, they are said to conform. **Conformity** occurs as a result of group pressure, real or imagined (Cialdini & Trost, 1998). You probably have experienced such group pressure when everyone around you stood to applaud a performance you thought was only mediocre. You might have conformed by standing as well, though no one told you to do so; the group's behavior creates a silent, but influential, pressure to follow suit. **Compliance**, in contrast, occurs when people adjust their behavior because of a request. The request can be either *explicit*, such as your brother saying, "Please pass the salt," or *implicit*, as when someone looks at you in a certain way to let you know it is time to start studying (Cialdini & Trost, 1998).

Mass Conformity The faithful who gather at Mecca, at the Vatican, and at other holy places around the world exemplify the power of religion and other social forces to produce conformity to group norms.

figure 18.2

Types of Stimulus Lines Used in Experiments by Asch

TRY THIS

Participants in Asch's experiments saw a new set of lines like these on each trial. The middle line in Part B matches the line in Part A, but when several of Asch's (1956) assistants chose an incorrect line, so did many of the participants. Try re-creating this experiment with four friends. Secretly ask three of them to choose the line on the left in Part B when you show this drawing, and then see if the fourth person conforms to the group norm. If not, do you think it was something about the person, the length of the incorrect line chosen, or both that led to nonconformity? Would conformity be more likely if the first three people were to choose the line on the right? (Read on for more on this possibility.)

Source: Asch (1955).

The Role of Norms

Conformity and compliance are usually generated by spoken or unspoken norms. In a classic experiment, Muzafer Sherif (1937) charted the formation of a group norm by taking advantage of a perceptual illusion, called the *autokinetic phenomenon*, whereby a stationary point of light in a pitch dark room appears to move. Estimates of the amount of movement tend to stay the same over time—if an observer is alone. But when Sherif tested several people at once, asking each person to say aloud how far the light moved on repeated trials, their estimates tended to converge; they had established a group norm. Even more important, when the individuals from the group were later tested alone, they continued to be influenced by this norm.

In another classic experiment, Solomon Asch (1956) examined how people would respond when they faced a norm that already existed but was obviously wrong. The participants in this experiment saw a standard line like the one in Figure 18.2(A); then they saw a display like that in Figure 18.2(B). Their task was to pick out the line in the display that was the same length as the one they had initially been shown.

Each participant performed this task in a small group of people who posed as fellow participants, but who were actually the experimenter's assistants. There were 2 conditions. In the control condition, the real participant responded first. In the experimental condition, the participant did not respond until after the assistants did. The assistants chose the correct response on 6 trials, but on the other 12 trials they all gave the same obviously incorrect response. So on 12 trials, each participant was confronted with a "social reality" created by a group norm that conflicted with the physical reality created by what the person could clearly see. Only 5 percent of the participants in the control condition ever made a mistake on this easy perceptual task. However, among participants who heard the assistants' responses before giving their own, about 70 percent made at least 1 error by conforming to the group norm. An analysis of 133 studies conducted in 17 countries reveals that conformity in Asch-type situations has declined somewhat in the United States since the 1950s, but it still occurs; it is especially likely in collectivist cultures, in which conformity to group norms is emphasized (Smith & Bond, 1999).

Pressure for conformity can even affect reports about personal experiences. In one study that used a procedure similar to Asch's, participants were shown a number of objects. Later, the same objects were shown again, along with some new ones, and the participants were asked to say whether they had seen each object in the previous display. When tested alone, the participants' memories were quite accurate, but hearing another person's opinion about which objects had or had not been shown before strongly affected their memory of which objects they had seen (Hoffman et al., 2001).

Why Do People Conform?

Why did so many people in Asch's experiment, and others like it, give incorrect responses when they were capable of near-perfect performance? One possibility is that they displayed *public conformity*, giving an answer they did not believe simply because it was the socially desirable thing to do. Another possibility is that they experienced *private acceptance*: Perhaps the participants used other people's responses as legitimate evidence about reality, were convinced that their own perceptions were wrong, and actually changed their minds. Morton Deutsch and Harold Gerard (1955) reasoned that if conformity disappeared when people gave their responses without identifying themselves, then Asch's findings must reflect public conformity, not private acceptance. In fact, conformity does decrease when people respond anonymously instead of publicly, but it is not eliminated (Deutsch & Gerard, 1955). People sometimes publicly produce responses that they do not believe, but hearing other people's responses also influences their private beliefs (Moscovici, 1985).

conformity Changing one's behavior or beliefs to match those of others, generally as a result of real or imagined, though unspoken, group pressure.

compliance Adjusting one's behavior because of an explicit or implicit request.

Why do group norms wield such power? Research suggests three influential factors (Cialdini & Trost, 1998). First, people are motivated to be correct, and norms provide information about what is right and wrong. This factor may help explain why some extremely disturbed or distressed people consider stories about suicide to be “social proof” that self-destruction is a reasonable way out of their problems (Cialdini, 1993). Second, people are motivated to be liked by others, and we generally like those who agree with us. Finally, norms influence the distribution of social rewards and punishments (Cialdini, 1995). From childhood on, people in many cultures learn that going along with group norms is good and earns rewards. (These positive outcomes presumably help compensate for not always being able to say or do exactly what we please.) People also learn that breaking a norm may bring punishments ranging from scoldings for small transgressions to imprisonment for violation of norms that have been translated into laws.

When Do People Conform?

People do not always conform to social influence. In the original Asch studies, for example, nearly 30 percent of the participants did not go along with the research assistants’ obviously erroneous judgments. Countless experiments have probed the question of what combinations of people and circumstances do and do not lead to conformity.

Ambiguity of the Situation Ambiguity, or uncertainty, is very important in determining how much conformity will occur. As the physical reality of a situation becomes less certain, people rely more and more on others’ opinions, and conformity to a group norm becomes increasingly likely (Aronson, Wilson, & Akert, 2002).

You can demonstrate this aspect of conformity on any street corner. First, create an ambiguous situation by having several people look at the sky or the top of a building. When passersby ask what is going on, be sure everyone excitedly reports seeing something interesting but fleeting—perhaps a faint light or a tiny, shiny object. If you are especially successful, conforming newcomers will begin persuading other passersby that there is something fascinating to be seen.

Unanimity and Size of the Majority If ambiguity contributes so much to conformity, why did so many of Asch’s participants conform to a judgment that was unambiguously wrong? The answer has to do with the *unanimity* of the group’s judgment and the number of people expressing it. Specifically, people experience great pressure to conform as long as the majority is unanimous. If even one other person in the group disagrees with the majority view, conformity drops greatly. When Asch (1951) arranged for just one assistant to disagree with the others, fewer than 10 percent of the real participants conformed. Once unanimity is broken, it becomes much easier to disagree with the majority, even if the other non-conformist does not agree with the person’s own view (Turner, 1991).

Conformity also depends on the size of the group. Asch (1955) demonstrated this phenomenon by varying the number of assistants in the group from one to fifteen. Conformity to incorrect norms grew as the number of people in the group increased. But most of the growth in conformity occurred as the size of the majority rose from one to about three or four members; further additions had little effect. Several years after Asch’s research, Bibb Latané (pronounced “lat-a-NAY”) sought to explain this phenomenon with his *social impact theory*. This theory holds that a group’s impact on an individual depends not only on group size but also on how important and close the group is to the person. And according to Latané (1981), the impact of increasing the size of a majority depends on how big the majority was originally. Increasing a majority from, say, two to three will have much more impact than increasing it from, say, sixty to sixty-one. The reason is that the increase from

sixty to sixty-one is psychologically much smaller than the change from two to three; it attracts far less notice in relative terms. Does this explanation sound familiar? The principles underlying it are similar to those of Weber's law, which, as described in the chapter on perception, governs our experience of changes in brightness, weight, and other physical stimuli.

Minority Influence Conformity can also result from minority influence, by which a numerical minority in a group influences the behavior or beliefs of a majority (Taylor, Peplau, & Sears, 2000). This phenomenon is less common than majority influence, but minorities can be influential, especially when they persist in their views and show agreement with one another (Moscovici, 1994). William Crano and his associates have found that whereas majority influence tends to affect people immediately and directly, minority influence is indirect; that is, minority-influenced change often takes a while to occur and may involve only a moderate adjustment of the majority view in the direction favored by the minority (Alvaro & Crano, 1997; Crano & Chen, 1998).

Gender Early research on conformity suggested that women conform more than men, but this gender difference stemmed mainly from the fact that the tasks used in those experiments were often more familiar to men than to women. This fact is important because people are especially likely to conform when they are faced with an unfamiliar situation (Cialdini & Trost, 1998). No male-female differences in conformity have been found in subsequent research using materials that are equally familiar to both genders (Maupin & Fisher, 1989).

So why do some people still perceive women as more conforming than men despite evidence to the contrary? Part of the answer may lie in their perception of the relative social status of men and women. People who think of women as having lower social status than men in most social situations are likely to see women as easier to influence, even though men and women conform equally often (Eagly, 1987).

Inducing Compliance

In the conformity experiments we have described, the participants experienced psychological pressure to conform to the views or actions of others, even though no one specifically asked them to do so. In contrast, *compliance* involves changing what you say or do because of a request.

How is compliance brought about? Many people believe that the direct approach is always best: If you want something, ask for it. But salespeople, political strategists, social psychologists, and other experts have learned that often the best way to get something is to ask for something else. Three examples of this strategy are the foot-in-the-door technique, the door-in-the-face procedure, and the low-ball approach.

The *foot-in-the-door technique* works by getting a person to agree to a small request and then gradually presenting larger ones. In the original experiment on this strategy, homeowners were asked to do one of two things. Some were asked to allow a large, unattractive "Drive Carefully" sign to be placed on their front lawn. Approximately 17 percent of the people approached in this way complied with the request. In the foot-in-the-door condition, however, homeowners were first asked only to sign a petition supporting legislation aimed at reducing traffic accidents. Several weeks later, when a different person asked these same people to put the "Drive Carefully" sign on their lawn, 55 percent of them complied (Freedman & Fraser, 1966).

Why should the granting of small favors lead to granting larger ones? First, people are usually far more likely to comply with a request that costs little in time, money, effort, or inconvenience. Second, complying with a small request makes people think of themselves as being committed to the cause or issue involved (Cialdini

minority influence A phenomenon whereby members of a numerical minority in a group alter the view of the majority.

Sign Here, Please Have you ever been asked to sign a petition in favor of a political, social, or economic cause? Supporters of these causes know that people who comply with this small request are the best people to contact later with requests to do more. Complying with larger requests is made more likely because it is consistent with the signer's initial commitment to the cause. If you were contacted after signing a petition, did you agree to donate money or become a volunteer?

& Trost, 1998). This change occurs through the processes of self-perception and cognitive dissonance discussed in the chapter on social cognition. In the study just described, participants who signed the petition might have thought, "I must care enough about traffic safety to do something about it." Compliance with the higher-cost request (displaying the sign) thus became more likely, because it was consistent with these people's self-perceptions and past actions (Eisenberg et al., 1987).

The foot-in-the-door technique can be quite effective. Steven Sherman (1980) created a 700 percent increase in the rate at which people actually volunteered to work for a charity simply by first getting them to say that, in a hypothetical situation, they would volunteer if asked. For some companies, the foot in the door is a request that potential customers merely answer a few questions; the request to buy something comes later. Others offer a small gift, or "door opener," as salespeople call it. Acceptance of the gift not only allows a foot in the door, but also may invoke the reciprocity norm: Many people who get something free of charge feel obligated to reciprocate by buying something (Cialdini, 2001). Recent research suggests, however, that small favors don't always lead to bigger ones. Specifically, if the request for the larger favor comes immediately after the initial request, people may be unlikely to comply with it (Guadagno et al., 2001).

The *door-in-the-face procedure* offers a second way of obtaining compliance (Cialdini, 2001; Reeves et al., 1991). This strategy begins with a request for a favor that is likely to be denied. The person making the request then concedes that asking for the initial favor was excessive and substitutes a lesser alternative—which was what the person really wanted in the first place! Because the person appears willing to compromise and because the new request seems modest in comparison with the first one, it is more likely to be granted than if it had been made at the outset. In this case, compliance appears to be due to activation of the reciprocity norm. The door-in-the-face strategy is often the basis of bargaining among political groups and between labor and management.

A third technique for gaining compliance, called the *low-ball approach*, is commonly used by car dealers and other businesses (Cialdini, 2001). The first step in this strategy is to obtain a person's oral commitment to do something, such as to purchase a car at a certain price. Once this commitment is made, the cost of fulfilling it is increased, often because of an "error" in computing the car's price. Why do buyers end up paying much more than originally planned for "low-balled" items? Apparently, once people commit themselves to do something, they feel obligated to follow through, especially when the person who obtains the initial commitment also

OK, OK, I'll Be Home by Midnight! The door-in-the-face approach is sometimes used successfully by teenagers who want their parents to comply with many kinds of requests. A teen who normally has a 10 P.M. curfew on school nights might be allowed to stay out until midnight (a "compromise" that actually was the original goal) after first asking for permission to be away overnight.

makes the higher-cost request (Burger & Petty, 1981). In other words, as described in relation to cognitive dissonance theory in the chapter on social cognition, people like to be consistent in their words and deeds. In this instance, it appears that people try to maintain a positive self-image by behaving in accordance with their initial oral commitment, even though it may cost them a great deal to do so.

figure 18.3

Studying Obedience in the Laboratory

In this photograph from Milgram's original experiment, a man is being strapped into a chair with electrodes on his arm. Although participants in the experiment do not know it, the man is actually one of the experimenter's research assistants and receives no shock.

Compliance involves a change in behavior in response to a request. In the case of **obedience**, the behavior change comes in response to a *demand* from an authority figure (Blass, 1999). In the 1960s, Stanley Milgram developed a laboratory procedure at Yale University to study obedience. In his first experiment, he used newspaper ads to recruit forty male volunteers between the ages of twenty and fifty. Among the participants were professionals, white-collar businessmen, and unskilled workers (Milgram, 1963).

Imagine you are one of the people who answered the ad. When you arrive for the experiment, you join a fifty-year-old gentleman who has also volunteered and has been scheduled for the same session. The experimenter explains that the purpose of the experiment is to examine the effects of punishment on learning. One of you—the “teacher”—will help the “learner” remember a list of words by administering an electrical shock whenever he makes a mistake. Then the experimenter turns to you and asks you to draw one of two cards out of a hat. Your card says “TEACHER.” You think to yourself that this must be your lucky day.

Now the learner is taken into another room and strapped into a chair, as shown in Figure 18.3. Electrodes are attached to his arms. You are shown a shock generator with 30 switches. The experimenter explains that the switch on the far left administers a mild, 15-volt shock and that each succeeding switch increases the shock by 15 volts; the switch on the far right delivers 450 volts. The far left section of the shock generator is labeled “slight shock.” Looking across the panel, you see “moderate shock,” “very strong shock,” and at the far right, “danger—severe shock.” The last 2 switches are ominously labeled “XXX.” The experimenter explains that you, the teacher, will begin by reading a list of word pairs to the learner. Then you will go through the list again, presenting just 1 word of each pair; the learner should indicate which word went with it. After the first mistake, you are to throw the switch to deliver 15 volts of shock. Each time the learner makes another mistake, you are to increase the shock by 15 volts.

You begin, following the experimenter's instructions. But after the learner makes his fifth mistake and you throw the switch to give him 75 volts, you hear a loud moan. At 90 volts, the learner cries out in pain. At 150 volts, he screams and asks to be let out of the experiment. You look to the experimenter, who says, “Proceed with the next word.”

No shock was actually delivered in Milgram's experiments. The learner was always an accomplice of the experimenter, and the moans and other signs of pain came from a prerecorded tape. But you do not know that. What would you do in this situation? Suppose you continue and eventually deliver 180 volts. The learner screams that he cannot stand the pain any longer and starts banging on the wall. The experimenter says, “You have no other choice; you must go on.” Would you continue? Would you keep going even when the learner begged to be let out of the experiment and then fell silent? Would you administer 450 volts of potentially deadly shock to a perfect stranger just because an experimenter demanded that you do so?

Figure 18.4 shows that only 5 participants in Milgram's experiment stopped before 300 volts, and 26 out of 40 participants (or 65 percent) went all the way to the 450-volt level. The decision to continue was difficult and stressful for the participants. Many protested repeatedly; but each time the experimenter told them to continue, they did so. Here is a partial transcript of what a typical participant said:

obedience Changing behavior in response to a demand from an authority figure.

figure 18.4**Results of Milgram's Obedience Experiment**

When Milgram asked a group of undergraduates and a group of psychiatrists how participants in his experiment would respond, they estimated that fewer than 2 percent would go all the way to 450 volts. In fact, 65 percent of the participants did so. What do you think you would have done in this situation?

Source: Milgram (1963).

[After throwing the 180-volt switch:] *He can't stand it. I'm not going to kill that man in there. Do you hear him hollering? He's hollering. He can't stand it. What if something happens to him? I'm not going to get that man sick in there. He's hollering in there. Do you know what I mean? I mean, I refuse to take responsibility. He's getting hurt in there. . . . Too many left here. Geez, if he gets them wrong. There are too many of them left. I mean, who is going to take responsibility if anything happens to that gentleman?*

[After the experimenter accepts responsibility:] *All right. . . .*

[After administering 240 volts:] *Oh, no, you mean I've got to keep going up the scale? No, sir, I'm not going to kill that man. I'm not going to give him 450 volts.*

[After the experimenter says, "The experiment requires that you go on":] *I know it does, but that man is hollering in there, sir.*

This participant administered shock up to 450 volts (Milgram, 1974, p. 74).

Factors Affecting Obedience

Milgram had not expected so many people to deliver such apparently intense shocks. Was there something about his procedure that produced this high level of obedience? To find out, Milgram and other researchers varied the original procedure in numerous ways. The overall level of obedience to an authority figure was usually quite high, but the degree of obedience was affected by several factors.

Experimenter Status and Prestige In Milgram's original study, the experimenter's status and prestige as a Yale University professor created two kinds of social power that affected the participants. The first was *expert social power*, which is the ability to influence people because they assume the person in power is a knowledgeable and responsible expert. The second was *legitimate social power*, which is the ability to influence people because they assume the person in power has the right or legitimate authority to tell them what to do (Blass & Schmitt, 2001).

To test the effects of reduced status and prestige, Milgram rented an office in a rundown building in Bridgeport, Connecticut. He then placed a newspaper ad for people to participate in research sponsored by a private firm; there was no mention of Yale. In all other ways, the experimental procedure was identical to the original.

Proximity and Obedience Milgram's research found that the close proximity of an authority figure is one of several factors that can enhance obedience to authority (Rada & Rogers, 1973). This proximity principle is used in the military, where no one is ever far away from the authority of a higher-ranking person.

Under these less prestigious circumstances, the level of obedience dropped, but not as much as you might expect; 48 percent of the participants continued to the maximum level of shock, compared with 65 percent in the original study. Milgram concluded that people still would obey instructions that could cause great harm to another even if the authority figure was not associated with a prestigious institution. Evidently, people's willingness to follow orders from an authority operates somewhat independently of the setting in which the orders are given.

The Behavior of Others To study how the behavior of fellow participants might affect obedience, Milgram (1965) created a situation in which there were apparently three teachers. Teacher 1 (in reality, a research assistant) read the words to the learner. Teacher 2 (another research assistant) indicated whether or not the learner's response was correct. Teacher 3 (the actual participant) was to deliver shock when mistakes were made. At 150 volts, when the learner began to complain that the shock was too painful, Teacher 1 refused to participate any longer and left the room. The experimenter asked him to come back, but he refused. The experimenter then instructed Teachers 2 and 3 to continue by themselves. The experiment continued for several more trials. However, at 210 volts, Teacher 2 said that the learner was suffering too much and refused to participate further. The experimenter then told Teacher 3 (the actual participant) to continue the procedure. In this case, only 10 percent of the participants (compared with 65 percent in the original study) continued to deliver shock all the way up to 450 volts. In other words, as research on conformity would suggest, the presence of others who disobey appears to be the most powerful factor in reducing obedience.

Personality Characteristics Were the participants in Milgram's original experiment heartless creatures who would have given strong shocks even if there had been no pressure on them to do so? Quite the opposite; most of them were nice people who were influenced by experimental situations to behave in apparently anti-social ways. In a later demonstration of the same phenomenon, college students playing the role of prison guards behaved with aggressive heartlessness toward other students who were playing the role of prisoners (Zimbardo, 1973).

Still, not everyone is equally obedient to authority. For example, people high in *authoritarianism* (a characteristic discussed in the chapter on social cognition) are more likely than others to comply with an experimenter's request to shock the

Civil Disobedience Not everyone is blindly obedient to authority. In 1955, Rosa Parks was arrested and fingerprinted in Montgomery, Alabama, after refusing an order to move to the “colored” section in the back of a segregated bus. Her courageous act of disobedience sparked the civil rights movement in the United States.

learner (Blass, 1991). Real-world support for this idea comes from recent findings that German soldiers who may have obeyed orders to kill Jews during World War II were higher on authoritarianism than other German men of the same age and background (Steiner & Fahrenberg, 2000).

Evaluating Milgram's Studies

How relevant are Milgram's thirty-five-year-old studies in today's world? Consider this fact: The U.S. Federal Aviation Administration attributes many commercial airline accidents to a phenomenon it calls “captainitis.” This phenomenon occurs when the captain of an aircraft makes an obvious error, but none of the other crew members is willing to challenge the captain's authority by pointing out the mistake. As a result, planes have crashed and people have died (Kanki & Foushee, 1990). A similar situation may have prevailed aboard the nuclear submarine *USS Greeneville* as it surfaced off the coast of Hawaii on February 9, 2001. The sub struck and sank a Japanese fishing boat, killing nine people, and a navy board of inquiry later found that crew members had been reluctant to challenge their captain's order to surface even though they felt he had not checked carefully enough for other vessels in the area (Myers, 2001). Obedience to authority may also have operated during the World Trade Center attack on September 11, 2001, when some people who had started for the exits returned to their offices after hearing an ill-advised public address announcement telling them to do so. Most of these people died as a result. Such events suggest that Milgram's findings are still relevant and important (Blass, 1999). Similar kinds of obedience have been observed in experiments conducted in many countries, from Europe to the Middle East, with female as well as male participants. In short, people appear to be as obedient today as they were when Milgram conducted his research (Blass, 1999; Smith & Bond, 1999).

Nevertheless, many aspects of Milgram's work still provoke debate. (For a summary of Milgram's results, plus those of studies on conformity and compliance, see “In Review: Types of Social Influence.”)

Following Ghastly Orders When authority figures issue orders, they tend to be obeyed, even when they are inhumane. In this case, for example, fifteen people, including a pregnant woman, were executed in the Colombian village of Los Angeles by gunmen whose leaders told them that the victims were rebel collaborators. And when the Taliban militia ruled Afghanistan, soldiers routinely carried out their superiors' orders to beat, or even execute, women for "offenses" such as seeking an education, laughing in public, or leaving home alone.

in review Types of Social Influence

Type	Definition	Key Findings
Conformity	A change in behavior or beliefs to match those of others	<p>In cases of ambiguity, people develop a group norm and then adhere to it.</p> <p>Conformity occurs because people want to be right, because they want to be liked by others, and because conformity to group norms is usually reinforced.</p> <p>Conformity usually increases with the ambiguity of the situation, as well as with the unanimity and psychological size of the majority.</p>
Compliance	A change in what is said or done because of a request	<p>Compliance increases with the foot-in-the-door technique, which begins with a small request and works up to a larger one.</p> <p>The door-in-the-face procedure can also be used. After making a large request that is denied, the person substitutes a less extreme alternative that was desired all along.</p> <p>The low-ball approach also elicits compliance. A person first obtains an oral commitment for something, then claims that only a higher-cost version of the original request will suffice.</p>
Obedience	A change in behavior in response to an explicit demand, typically from an authority figure	<p>People may inflict great harm on others when an authority demands that they do so.</p> <p>Even though people obey orders to harm another person, they often agonize over the decision.</p> <p>People are most likely to disobey orders to harm someone else when they see another person disobey.</p>

Ethical Questions Although the “learners” in Milgram’s experiment suffered no discomfort, the participants did. Milgram (1963) observed participants “sweat, stutter, tremble, groan, bite their lips, and dig their fingernails into their flesh” (p. 375). Against the potential harm inflicted by Milgram’s experiments stand the potential gains. For example, people who learn about Milgram’s work often take his findings into account when deciding how to behave in social situations (Sherman, 1980). But even if social value has come from Milgram’s studies, the question remains: Was it ethical for Milgram to treat his participants as he did?

In the years before his death in 1984, Milgram defended his experiments (e.g., Milgram, 1977). He argued that his debriefing of the participants after the experiment prevented any lasting harm. For example, to demonstrate that their behavior was not unusual, Milgram told them that most people went all the way to the 450-volt level. He also explained that the learner did not experience any shock; in fact, the learner came in and chatted with each participant. On a later questionnaire, 84 percent of the participants said that they had learned something important about themselves and that the experience had been worthwhile. Milgram argued, therefore, that the experience was actually a positive one. Still, today’s committees charged with protecting human participants in research would be unlikely to approve Milgram’s experiments, and less controversial ways to study obedience have now been developed (Sackoff & Weinstein, 1988).

Questions of Meaning Do Milgram’s dramatic results mean that most people are putty in the hands of authority figures and that most of us would blindly follow inhumane orders from our leaders? Some critics have argued that other factors besides obedience to authority were responsible for the behavior of Milgram’s participants and that the social-influence processes identified in his studies might not explain obedience in the real world. For example, Leonard Berkowitz (1999) pointed out that Milgram’s studies cannot explain why, during World War II, many German concentration camp guards not only obeyed their superiors’ orders to kill prisoners, but carried out those orders in the most sadistic and inhumane manner possible. Their actions, Berkowitz said, went far beyond simple obedience to authority.

Most psychologists believe that Milgram did more than highlight the phenomenon of obedience. He appears to have demonstrated a basic truth about human behavior—namely, that under certain circumstances, human beings are capable of unspeakable acts of brutality toward other humans. Sadly, examples abound. And one of the most horrifying aspects of human inhumanity—whether it is the Nazis’ campaign of genocide against Jews sixty years ago or the campaigns of terror under way today—is that the perpetrators are not necessarily demented, sadistic fiends. Most of them are, in many respects, “normal” people who have been influenced by economic and political situations, and the persuasive power of their leaders, to behave in a demented and fiendish manner.

In short, inhumanity can occur even without pressure for obedience. For example, a good deal of people’s aggressiveness toward other people appears to come from within. In the next section, we consider human aggressiveness and some of the circumstances that influence its expression.

Aggression

Aggression is an action intended to harm another person. In the United States, the incidence of homicide and other violent crimes has dropped substantially in the last few years, but acts of violence are still all too common. In 1999, more than 8 million people in the United States were victims of violent crime. Just under 1 in every 1,000 women was raped and slightly more than 1 in every 1,000 young African American men was murdered (U.S. Department of Justice, 2001). One of the most frightening aspects of these figures is that many of the aggressors and victims were

aggression An act that is intended to cause harm to another person.

LINKAGES (a link to
Introducing Psychology)

not strangers. About 45 percent of the murder victims knew their killers, and about 60 percent of rapists were romantic partners, friends, relatives, or acquaintances of their victims (U.S. Department of Justice, 2001). About one-third of married people in the United States display aggression toward each other that ranges from pushing, shoving, and slapping to beatings and the threatened or actual use of weapons (Archer, 2000; Heyman & Neidig, 1999).

Why Are People Aggressive?

An early theory of human aggression was offered by Sigmund Freud, who suggested it was partly due to *Thanatos*, the death instincts described in the chapter on personality. Freud proposed that aggression is an instinctive biological urge that gradually builds up in everyone and must be released. Sometimes, he said, release takes the form of physical or verbal abuse against others; at other times, the aggressive impulse is turned inward and leads to suicide or other self-damaging acts.

A slightly more complicated view is offered by evolutionary psychologists. As discussed in the introductory chapter, these psychologists believe that human social behavior is related to our evolutionary heritage. From this perspective, aggression is thought to have helped prehistoric people compete for mates, thus ensuring survival of their genes in the next generation. Through the principles of natural selection, then, aggressive tendencies were passed on through successive generations. Some evolutionary psychologists believe that even now, aggression sometimes occurs because it promotes the survival of the aggressor's genes (e.g., Malamuth & Addison, 2001).

Today, evolutionary theories of the origins of aggression are quite popular, but even ardent evolutionary theorists realize that “nature” alone cannot fully account for aggression. “Nurture,” in the form of environmental factors, also plays a large role in when and why people are aggressive. How do we know this? For one thing, there are large differences in aggression from culture to culture. In the Philippines, for example, the murder rate is forty-six times higher than in China or Finland, and it is almost nine times higher in the United States than in those latter two countries (Triandis, 1994). In fact, the homicide rate is higher in the United States than in any other industrialized nation (Geen, 1998a). These data suggest that even if aggressive *impulses* are universal, the emergence of aggressive *behavior* reflects an interplay of nature and nurture (Malamuth & Addison, 2001). No equation can predict when people will be aggressive, but years of research have revealed a number of important biological, learning, and environmental factors that combine in various ways to produce aggression in various situations.

Genetic and Biological Mechanisms The evidence for hereditary influences on aggression is strong, especially in animals (Cairns, Garipey, & Hood, 1990). In one study, the most aggressive members of a large group of mice were interbred; then the most aggressive of their offspring were also interbred. After this procedure was followed for twenty-five generations, the resulting animals would immediately attack any mouse put in their cage. Continuous inbreeding of the least aggressive members of the original group produced animals that were so nonaggressive that they would refuse to fight even when attacked (Lagerspetz & Lagerspetz, 1983). Research on human twins reared together or apart suggests that there is a genetic component to aggression in people as well (Tellegen et al., 1988). However, other research suggests that people do not necessarily inherit the tendency to be aggressive; instead, they may inherit certain temperaments, such as impulsiveness, that in turn make aggression more likely (Baron & Richardson, 1994).

Several parts of the brain influence aggression (Anderson & Anderson, 1998). One is the limbic system, which includes the amygdala, the hypothalamus, and related areas (see Figure 3.14 in the chapter on biological aspects of psychology). Damage to these structures may produce *defensive aggression*, which includes heightened

figure 18.5

Testosterone and Aggression

In the study illustrated here, the children of women who had taken testosterone during pregnancy to prevent miscarriage became more aggressive than the mothers' other children of the same sex who had not been exposed to testosterone during prenatal development. This outcome held for both males and females.

Source: Data from Reinisch, Ziemba-Davis, & Sanders (1991).

aggressiveness to stimuli that are not usually threatening or a decrease in the responses that normally inhibit aggression (Coccaro, 1989; Eichelman, 1983). The cerebral cortex may also be involved in aggression (e.g., Pietro et al., 2000; see Figure 3.16). One study found that the prefrontal area of the cortex metabolized glucose significantly more slowly in murderers than in nonmurderers (Raine et al., 1994).

Hormones such as *testosterone*—the masculine hormone that is present in both sexes—may also play an important role in aggression (Dabbs & Dabbs, 2001). Experiments have shown that aggressive behavior increases or decreases dramatically with the level of testosterone in the human bloodstream (Pope, Kouri, & Hudson, 2000; Yates, 2000). Among criminals, those who commit violent crimes have higher levels of testosterone than those whose crimes are nonviolent. And among murderers, those with higher levels of testosterone are more likely than others to have known their victims and to have planned their crimes before committing them (Dabbs, Riad, & Chance, 2001).

Testosterone may have its most significant and durable influence not so much through its day-to-day variations as through its impact on early brain development. One natural test of this hypothesis occurred when pregnant women were given testosterone in an attempt to prevent miscarriages. Accordingly, their children were exposed to high doses of testosterone during prenatal development. Figure 18.5 shows that these children grew up to be more aggressive than their same-sex siblings who were not exposed to testosterone during prenatal development (Reinisch, Ziemba-Davis, & Sanders, 1991).

Drugs that alter central nervous system functioning can also affect the likelihood that a person will act aggressively. Alcohol, for example, can substantially increase some people's aggressiveness. Canadian researchers have found that in almost 70 percent of the acts of aggression they studied, the aggressors had been drinking alcohol. And the more alcohol the aggressors consumed, the more aggressive they were (Wells, Graham, & West, 2000). No one knows exactly why alcohol increases aggression, but research suggests that the drug may affect areas of the brain that normally inhibit aggressive responses (Lau, Pihl, & Peterson, 1995).

Research on the effects of other drugs on aggression has produced some surprising findings. One might expect, for example, that using stimulants would increase aggressiveness and that taking tranquilizers would reduce it, but the opposite appears to be true. Whereas amphetamine stimulants do not usually make people more aggressive, opiates (e.g., heroin and morphine) and some tranquilizers may do so (Taylor & Hulsizer, 1998). No one knows why heroin users are more likely than amphetamine users to be aggressive. Some have suggested that heroin addicts' aggression reflects their desperate need to get money, by any means, to buy more drugs. But if this were so, we should also see increased aggression among people who are addicted to amphetamines and cocaine—because these addictions, too, are very expensive. Further, ingesting opiates increases people's aggressiveness even in controlled laboratory settings (Taylor & Hulsizer, 1998), suggesting that these drugs have biochemical effects that lead directly to aggression. The nature of these effects is presently unknown.

Learning and Cultural Mechanisms

Cross-cultural research makes it clear that although biological factors may increase or decrease the likelihood of aggression, learning also plays a role. Aggressive behavior is much more common in individualist than in collectivist cultures, for example (Oatley, 1993). Cultural differences in the expression of aggression appear to stem in part from differing cultural values. For example, in contrast to many so-called "advanced" peoples, the Utku, an Inuit culture, view aggression in any form as a sign of social incompetence. In fact, the Utku word for "aggressive" also means "childish" (Oatley, 1993). The effects of culture on aggression can also be seen in the fact that the incidence of aggression in a given culture changes over time as cultural values change (Matsumoto, 2000).

Aggression can even differ in different areas of the same country. Consider the fact that more males in the southern U.S. states commit homicide than do males in the northern states (U.S. Department of Justice, 2001). As discussed later, this regional difference in the homicide rate may be related to the South's higher temperatures, but Richard Nisbett and his colleagues (Nisbett, 1993; Cohen & Nisbett, 1997) have proposed that it is due to a *culture of honor* that is more commonly endorsed by southern males. One key aspect of this cultural orientation is the need to defend one's honor, with violence if necessary, in response to a perceived insult. Studies testing this notion have in fact found that southern-born college students reacted much more angrily to a provocation than did northern-born students (Cassel & Bernstein, 2001; Cohen et al., 1996).

People also learn many aggressive responses by watching others (Bushman & Anderson, 2001). Children, in particular, learn and perform many novel aggressive responses that they see modeled by others (Bandura, 1983). Albert Bandura's "Bobo" doll experiments, which are described in the chapter on learning, provide impressive demonstrations of the power of observational learning. The significance of observational learning is highlighted by studies of the effects of televised violence, also discussed in that chapter. For example, the amount of violent content watched on television by eight-year-olds predicts aggressiveness in these children even fifteen years later (Huesmann et al., 1997). Fortunately, not everyone who sees aggression becomes aggressive; individual differences in temperament, the modeling of nonaggressive behaviors by parents, and other factors can temper the effects of violent television. Nevertheless, observational learning does play a significant role in the development and display of aggressive behavior (Bushman & Anderson, 2001).

Immediate reward or punishment can also alter the frequency of aggressive acts; people become more aggressive when rewarded for aggressiveness and less aggressive when punished for aggression (Geen, 1998a). In short, a person's accumulated experiences—including culturally transmitted teachings—combine with daily rewards and punishments to influence whether, when, and how aggressive acts occur (Baron & Richardson, 1994).

When Are People Aggressive?

In general, people are more likely to be aggressive when they are both physiologically aroused and experiencing strong emotions such as anger (Geen, 1998b). People tend either to lash out at those who make them angry or to displace their anger onto

LINKAGES (a link to
Motivation and Emotion)

Following Adult Examples Learning to express aggression is especially easy for children, who, like this child at an anti-American demonstration in Pakistan in October 2001, see aggressive acts modeled for them all too often.

defenseless targets such as children or pets. However, aggression can also be made more likely by other forms of emotional arousal. One emotion that has long been considered to be a major cause of aggression is *frustration*, which occurs when we are prevented from reaching some goal.

Frustration and Aggression Suppose that a friend interrupts your studying for an exam by coming over to borrow a book. If things have been going well that day and you are feeling confident about the exam, you are likely to be friendly and accommodating. But what if you are feeling frustrated because your friend's visit represents the fifth interruption in the last hour? Under these emotional circumstances, you may react aggressively, perhaps snapping at your startled visitor for not calling ahead.

Your aggressiveness in this situation conforms to the predictions of the **frustration-aggression hypothesis**, originally developed by John Dollard and his colleagues (Dollard et al., 1939). They proposed that frustration always results in aggression and, conversely, that aggression will not occur unless a person is frustrated. Research on this hypothesis, however, has shown that it is too simple and too general. For one thing, frustration sometimes produces depression and withdrawal, not aggression (Berkowitz, 1998). In addition, not all aggression is preceded by frustration (Berkowitz, 1994). In many of the experiments described earlier, for example, participants were not frustrated, but they still made aggressive responses.

After many years of research, Leonard Berkowitz (1998) suggested some substantial modifications to the frustration-aggression hypothesis. First, he proposed that it may be *stress* rather than frustration per se that can produce a readiness to act aggressively. Once this readiness exists, cues in the environment that are associated with aggression will often lead a person to behave aggressively. The cues might be guns or knives, televised scenes of people arguing, and the like. Neither stress alone nor the cues alone are sufficient to set off aggression. When combined, however, they often do set it off. Support for this aspect of Berkowitz's theory has been quite strong (Malamuth & Addison, 2001).

Second, Berkowitz argues that the direct cause of most kinds of aggression is *negative affect*, or unpleasant emotion, and that whether it is caused by frustrating circumstances or other sources, the greater the negative affect, the stronger is the readiness to respond aggressively (Berkowitz, 1998). For example, negative affect can stem from pain; and research suggests that people in pain do tend to become aggressive, no matter what caused their pain. In one study, female students whose hands were placed in painfully cold water became more aggressive toward other students than women whose hands were in water of room temperature (Berkowitz, 1998).

Generalized Arousal Imagine you have just jogged three miles. You are hot, sweaty, and out of breath, but you are not angry. Still, the physiological arousal caused by jogging may increase the probability that you will become aggressive if, say, a passerby shouts an insult (Zillmann, 1988). Why? The answer lies in a phenomenon described in the chapter on motivation and emotion: Arousal from one experience may carry over to an independent situation, producing what is called *transferred excitation*. So the physiological arousal caused by jogging may intensify your reaction to an insult (Geen, 1998b).

By itself, however, generalized arousal does not lead to aggression. It is most likely to produce aggression when the situation contains some reason, opportunity, or target for aggression (Zillmann, 1988). In one study, for example, people engaged in two minutes of vigorous exercise. Then they had the opportunity to deliver electrical shock to another person. The participants chose high levels of shock only if they were first insulted (Zillmann, Katcher, & Milavsky, 1972). Apparently, the arousal resulting from the exercise made aggression more likely; the insult "released" it. These findings are in keeping with the notion that aggression is not

frustration-aggression hypothesis A proposition that frustration always leads to some form of aggressive behavior.

caused solely by a person's characteristics or by the particular situation a person is in; rather, the incidence and intensity of aggression are determined by the joint influence of individual characteristics and environmental circumstances.

THINKING CRITICALLY

Does Pornography Cause Aggression?

In both men and women, sexual stimulation produces strong, generalized physiological arousal, especially in the sympathetic nervous system. If arousal in general can make a person more likely to be aggressive (given a reason, opportunity, or target), could stimuli that create sexual excitement be dangerous? In particular, does viewing pornographic material make people more likely to be aggressive? Over the years, numerous scholars had concluded that there was no evidence for an overall relationship between any type of antisocial behavior and mere exposure to pornographic material (Donnerstein, 1984b). However, in 1986 the U.S. Attorney General's Commission on Pornography reexamined the question and concluded that pornography is dangerous.

● What am I being asked to believe or accept?

Specifically, the commission proposed that there is a causal link between viewing erotic material and several forms of antisocial behavior, including sexually related violent crimes.

● What evidence is available to support the assertion?

The commission cited several types of evidence in support of its conclusion. First, there was the testimony of men convicted of sexually related crimes. Rapists, for example, are unusually heavy consumers of pornography, and they often say that they were aroused by erotic material immediately before committing a rape (Silbert & Pines, 1984). Similarly, child molesters often view child pornography immediately before committing their crimes (Marshall, 1989).

In addition, the commission cited experimental evidence that men who are most aroused by aggressive themes in pornography are also the most potentially sexually aggressive. One study, for example, showed that men who said they could commit a rape became sexually aroused by scenes of rape and less aroused by scenes of mutually consenting sex; this was not true for men who said they could never commit a rape (Malamuth & Check, 1983).

Perhaps the most compelling evidence cited by the commission, however, came from transferred excitation studies. In a typical study of this type, men are told that a person in a separate room (actually a research assistant) will be performing a learning task and that they are to administer an electrical shock every time the person makes a mistake. The intensity of shock can be varied (no shock actually reaches the assistant), but participants are told that changing the intensity will not affect the speed of learning. So the shock intensity (and presumed pain) that the participants choose to administer is taken as an index of aggressive behavior. Some participants watch a sexually explicit film before beginning the learning trials, and some do not. The arousal created by the film appears to transfer into aggression, especially when the arousal is experienced in a negative way. For example, after watching a film in which several men have sex with the same woman, the participants became aroused but tended to label the experience as somewhat unpleasant. Their aggressiveness during the learning experiment was greater than that demonstrated by men who did not watch the film (Donnerstein, 1984b).

● Are there alternative ways of interpreting the evidence?

The commission's interpretation of evidence was criticized on several counts. First, critics argued that some of the evidence should be given little weight. In particular,

how credible is the testimony of convicted sex offenders? It may reflect self-serving attempts to lay the blame for their crimes on pornography. These reports cannot establish that exposure to pornography causes aggression. In fact, it may be that pornography partially *satisfies* sex offenders' aggressive impulses rather than creating them (Aronson, Wilson, & Akert, 2002). Similarly, the fact that potential rapists are most aroused by rape-oriented material may show only that they prefer violence-oriented pornography, not that such materials *created* their impulse to rape.

What about the evidence from transferred excitation studies? To interpret these studies, you need to know that the pornography that led to increased aggression contained violence as well as sex; the sexual activity depicted was painful for, or unwanted by, the woman. So the subsequent increase in aggression could have been due to the transfer of sexual arousal, the effects of observing violent behavior, or the effects of seeing sex combined with violence (Donnerstein, Slaby, & Eron, 1995).

In fact, several careful experiments have found that highly arousing sexual themes, in and of themselves, do not produce aggression. When men in transferred excitation studies experience pleasant arousal by viewing a film depicting nudity or mutually consenting sexual activity, their subsequent aggression is actually less than when they viewed no film or a neutral film (Lord, 1997). In short, the transferred excitation studies might be interpreted as demonstrating not that sexually arousing material causes aggression but that portrayals of sexual *violence* influence aggressiveness.

• **What additional evidence would help to evaluate the alternatives?**

Two types of evidence are needed to understand more clearly the effects of pornography on aggression. First, because pornography can include sexual acts, aggressive acts, or both, the effects of each of these components must be more carefully examined. Second, factors affecting men's reactions to pornography, particularly pornography that involves violence, must be more clearly understood. Work is in progress on each of these fronts.

Aggressive themes—whether specifically paired with sexual activity or not—do appear to increase subsequent aggression (Bushman & Anderson, 2001). Research has focused on *aggressive pornography*, which contains sexual themes but also scenes of violence against women (Linz, Wilson, & Donnerstein, 1992). In laboratory experiments, men often administer higher levels of shock to women after viewing aggressive pornographic films as opposed to neutral films. Yet there is no parallel increase in aggression against other men, indicating that the films don't create a generalized increase in aggression but do create an increase in aggressiveness directed toward women (Aronson, Wilson, & Akert, 2002). Similarly, viewing aggressive pornography that depicts the *rape myth*—in which the victim of sexual violence appears to be aroused by the aggression—usually leads men to become less sympathetic toward the rape victim and more tolerant of aggressive acts toward women (Donnerstein & Linz, 1995). In general, sexually explicit films that do not contain violence have no effect on attitudes toward rape (Linz, Donnerstein, & Penrod, 1987).

Pornography is widely available, but are all men who view it equally likely to become rapists? The evidence available so far suggests that the answer is no. Whether aggressive pornography alters men's behavior and attitudes toward women depends to some extent on the men. A national study of more than 2,700 men in the United States examined how three factors—a history of sexual promiscuity, feelings of hostility toward women, and the consumption of pornography—were related to sexual aggression against women (Malamuth, 1998). Among men *low* in promiscuity and hostility, viewing pornography was not associated with sexual aggression; among men who were *high* in promiscuity and hostility, though, there was such an association. Specifically, 72 percent of the men who were high on all three factors had actually engaged in sexually aggressive acts (see Figure 18.6).

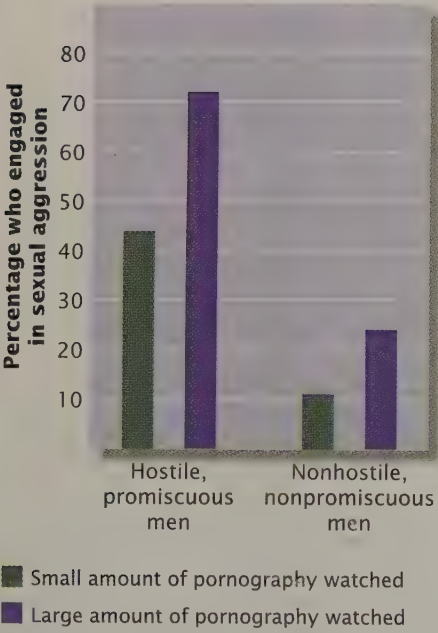

figure 18.6
Pornography and Sexual Aggression
Extensive exposure to pornography does not by itself make most men more likely to engage in sexual aggression. However, among men who are hostile toward women and have a history of sexual promiscuity, those who watch a lot of pornography are much more likely to engage in sexual aggression.

figure 18.7

Effects of Temperature on Aggression

Studies from around the world indicate that aggressive behaviors are most likely to occur during hot summer months. These studies support the idea that environmental factors can affect aggression.

Source: Anderson & Anderson (1998).

Crowding and Aggression Studies of prisons suggest that as crowding increases, so does aggression (Paulus, 1988). Accordingly, environmental psychologists are working with architects on the design of prisons that minimize the sense of crowding and that ideally may help prevent some of the violence that endangers staff and prisoners.

What conclusions are most reasonable?

The attorney general's commission appeared to ignore numerous studies showing that the relationship between sexual arousal and aggression is neither consistent nor simple (Seto, Maric, & Barabee, 2001). Analysis of this relationship reveals the importance of distinguishing between pornography in general and aggressive pornography in particular. Overall, there is no reason to assume that sexual arousal created by nonaggressive pornography is associated with aggressive behavior. In fact, for most people, sexual arousal and aggression remain quite separate. However, aggressive pornography is associated with violence against women, so there is reason for concern over the impact of sexual violence commonly seen on television and in films—especially “slasher” movies. Amazing as it may seem, in the United States such films are sometimes given less restrictive ratings (R or even PG-13) than films that are nonviolent but erotic.

Although pornography has little impact on most people, certain segments of the population do seem to be affected by it. Men who are inclined to abuse and exploit women are also inclined to watch a lot of pornography. And watching a lot of pornography can increase the likelihood of their sexually abusing a woman (Malamuth, Addison, & Koss, 2001). In short, pornography per se is probably not a cause of violence against women, but in combination with other factors it can play a role in sexual aggression.

Environmental Influences on Aggression The link between stress and aggressive behavior points to the possibility that stressful environmental conditions can make aggressive behavior more likely (Anderson, 2001). This possibility is one of the research topics in **environmental psychology**, the study of the relationship between people's physical environment and their behavior (Sommer, 1999). One aspect of the environment that clearly affects social behavior is the weather, especially temperature. High temperature is a source of stress and arousal, so it might be expected to correlate with aggressiveness. The results of many studies conducted in several countries show that many kinds of aggressive behavior are indeed more likely to occur during hot summer months than at any other time of the year (Anderson, et al., 2000; see Figure 18.7).

environmental psychology The study of the relationship between behavior and the physical environment.

Air pollution is another source of stress, and it can influence whether a person displays aggression (Holahan, 1986). For example, people tend to become more aggressive when breathing air that contains ethyl mercaptan, a mildly unpleasant-smelling pollutant common in urban areas (Rotton et al., 1979). A study conducted in Dayton, Ohio, found that the frequency of aggressive family disturbances increased along with the ozone level in the air (Rotton & Frey, 1985). And in laboratory studies, nonsmokers are more likely to become aggressive when breathing smoke-filled rather than clean air (Zillmann, Baron, & Tamborini, 1981). Long-term exposure to toxins such as lead has also been associated with increased aggression (Needleman, 1996).

Noise—usually defined as any unwanted and uncontrollable sound (Bell et al., 1996)—also tends to make people more likely to display aggression, especially if the noise is unpredictable and irregular (Geen & McCown, 1984). Living arrangements, too, can influence aggressiveness. Compared with the tenants of crowded apartment buildings, those in buildings with relatively few residents are less likely to behave aggressively (Bell et al., 1996). This difference appears to be due in part to how people feel when they are crowded. Crowding tends to create physiological arousal and to make people tense, uncomfortable, and more likely to report negative feelings (Oskamp & Schultz, 1998). This arousal and tension can influence people to like one another less and to be more aggressive. One study of juvenile delinquents found that the number of behavior problems they displayed (including aggressiveness) was directly related to how crowded their living conditions had become (Ray et al., 1982).

Altruism and Helping Behavior

Like all acts of terrorism, the 2001 attacks on the World Trade Center and the Pentagon were horrifying examples of human behavior at its worst. But like all tragedies, they drew responses that provide inspiring examples of human behavior at its best. Michael Benfante and John Cerqueira were working in the World Trade Center when one of the hijacked planes struck their building. They headed for a stairwell, but they did not just save themselves. Although it slowed their own escape, they chose to carry Tina Hansen, a wheelchair-bound co-worker, down sixty-eight flights of stairs to safety. David Theall was in his Pentagon office when another hijacked plane hit not far from his desk. He could have escaped the rubble

Two of Many Heroes Along with his colleague Michael Benfante, John Cerqueira (shown here) risked his life on September 11, 2001, to help a handicapped co-worker escape from the 68th floor of the World Trade Center. Hundreds of other heroic acts of helping took place that day, and less dramatic examples occur every day, all over the world.

A Young Helper Even before their second birthday, some children offer help to those who are hurt or crying by snuggling, patting, or offering food or even their own teddy bears.

immediately, but he first located a dazed officemate and led him, along with seven other co-workers, to safety. And no one will ever forget the heroism of the hundreds of New York City firefighters, police officers, and emergency workers who risked their lives, and lost their lives, while trying to save others. Acts of selflessness and sacrifice were common that day, and in the days and weeks and months that followed. Police officers, medical personnel, search-and-rescue specialists, and just ordinary people came to New York from all over the United States to help clear wreckage, look for survivors, and recover bodies. More than \$1 billion in donations to the Red Cross and other charitable organizations poured in to help victims; one celebrity telethon raised \$150 million in two hours.

All of these actions are examples of **helping behavior**, which is defined as any act that is intended to benefit another person. Helping can range from picking up dropped packages to donating a kidney. Closely related to helping is **altruism**, an unselfish concern for another's welfare (Dovidio & Penner, 2001). In the following sections we examine some of the reasons for helping and altruism, along with some of the conditions under which people are most likely to help others.

Why Do People Help?

The tendency to help others begins early, although at first it is not spontaneous. In most cultures, very young children generally help others only when they are asked to do so or are offered a reward (Grusec, 1991). Still, Carolyn Zahn-Waxler and her associates (1992) found that almost half of the two-year-olds they observed acted helpfully toward a friend or family member. As they grow older, children use helping behavior to gain social approval, and their efforts at helping become more elaborate. The role of social influence in the development of helping is seen as children follow examples set by people around them; their helping behaviors are shaped by the norms established by their families and the broader culture (Grusec & Goodnow, 1994). In addition, children are praised and given other rewards for helpfulness but are scolded for selfishness. Eventually children come to believe that being helpful is good and that they are good when they are helpful. By the late teens, people often help others even when no one is watching and no one will know that they did so (Cialdini, Baumann, & Kenrick, 1981). There are three major theories about why people help even when they cannot expect any external rewards for doing so.

Arousal: Cost-Reward Theory One psychological model that attempts to explain why people help is called the **arousal: cost-reward theory** (Piliavin et al., 1981). This theory proposes that people find the sight of a victim distressing and anxiety provoking, and that this experience motivates them to do something to reduce the unpleasant arousal. Several studies have shown that all else being equal, the more physiologically aroused bystanders are, the more likely they are to help someone in an emergency (Dovidio et al., 1991; Schroeder et al., 1995). Before rushing to a victim's aid, however, the bystander will first evaluate two aspects of the situation: the costs associated with helping and the costs (to the bystander and the other person) of not helping. Whether or not the bystander actually helps depends on the outcome of this evaluation (Dovidio et al., 1991). If the costs of helping are low (as when helping someone pick up a dropped grocery bag) and the costs of not helping are high (as when the other person is physically unable to do this alone), the bystander will almost certainly help. However, if the costs of helping are high (as when the task is to load a heavy air conditioner into a car) and the costs of not helping are low (as when the person is strong enough to manage the task alone), the bystander is unlikely to offer help. This theory is attractive partly because it is comprehensive enough to provide a conceptual framework for explaining a number of research findings on the factors that affect helping. Let's consider some of these factors.

helping behavior Any act that is intended to benefit another person.

altruism An unselfish concern for another's welfare.

arousal: cost-reward theory A theory attributing people's helping behavior to their efforts to reduce the unpleasant arousal they feel in the face of someone's need or suffering.

One factor is the *clarity of the need for help*, which has a major impact on whether people provide help (Dovidio et al., 1991). In one study, undergraduate students were waiting alone in a campus building when a window washer appeared to suffer an accident. The man screamed as he and his ladder fell to the ground; then he began to clutch his ankle and groan in pain. All of the students looked out a window to see what had happened, but only 29 percent of them did anything to help. Other students experienced the same situation with one important difference: The man *said* he was hurt and needed help. In this case, more than 80 percent of the students came to his aid (Yakimovich & Saltz, 1971). Why? Apparently, this one additional cue eliminated any ambiguity about whether the person needed help. This cue also raised the perceived costs to the victim of not offering help; as these costs become higher, helping becomes more likely. If this laboratory study does not seem realistic enough, consider the case of a sixty-two-year-old woman in Darby, Pennsylvania, who was walking to the grocery store in March 2000 when she was pushed from behind by an attacker. She fended him off and then did her shopping as usual. It was only when she got home and her daughter saw the handle of a knife protruding from her back that she realized that the assailant had stabbed her! No one in the grocery store said anything to her about the knife, let alone offered to help. Why? Perhaps because the woman didn't say or do anything to suggest that help was needed.

The *presence of others* also has a strong influence on the tendency to help. However, their presence actually tends to inhibit helping behavior. One of the most highly publicized examples of this phenomenon was the Kitty Genovese incident, which occurred on a New York City street in 1964. During a thirty-minute struggle, a man stabbed Genovese repeatedly, but none of the dozens of neighbors who witnessed the attack intervened or even called the police until it was too late to save her life. A similar case occurred on November 27, 2000, in London, when a ten-year-old boy who had been stabbed by members of a street gang lay ignored by passersby as he bled to death. After each case, journalists and social commentators expressed dismay about the apathy and callousness that seems to exist among people who live in big cities. But psychologists believe that something about the situation surrounding such events deters people from helping.

The numerous studies of helping behavior stimulated by the Genovese case revealed a phenomenon that may explain the inaction of Genovese's neighbors and those passersby in London. This phenomenon is known as the *bystander effect*: usually, as the number of people who witness an emergency increases, the likelihood that one of them will help decreases (Dovidio & Penner, 2001). One explanation for why the presence of others often reduces helping is that each person thinks someone else will help the victim. That is, the presence of other bystanders allows each individual to experience a *diffusion of responsibility* for taking action, which lowers the costs of not helping (Schroeder et al., 1995).

The degree to which the presence of other people will inhibit helping may depend on who those other people are. When they are strangers, perhaps poor communication inhibits helping. People often have difficulty speaking to strangers, particularly in an emergency, and without speaking, they have difficulty knowing what the others intend to do. According to this logic, if people are with friends rather than strangers, they should be less uncomfortable, more willing to discuss the problem, and thus more likely to help.

In one experiment designed to test this idea, an experimenter left a research participant in a waiting room, either alone, with a friend, with a stranger, or with a stranger who was an assistant to the experimenter (Latané & Rodin, 1969). The experimenter then stepped behind a curtain into an office. For a few minutes, she could be heard opening and closing the drawers of her desk, shuffling papers, and so on. Then there was a loud crash, and she screamed, "Oh, my god . . . My foot, I . . . I can't move it. Oh, my ankle . . . I can't get this . . . thing off me." Then the participant heard her groan and cry.

Diffusion of Responsibility Does the man on the sidewalk need help? The people nearby probably are not sure and might assume that if he does, someone else will assist him. Research on factors affecting helping and altruism suggests that if you ever need help in an emergency, especially if a number of others are present, it is important not only to clearly ask for help but also to tell a specific onlooker to take specific action (for example, "You, in the yellow shirt, please call an ambulance!").

Would the participant go behind the curtain to help? Once again, people were most likely to help if they were alone. When one other person was present, participants were more likely both to communicate with one another and to offer help if they were friends than if they were strangers. When the stranger was the experimenter's assistant (who had been instructed not to help), very few participants offered to help. Other studies have confirmed that bystanders' tendency to help increases when they know one another (Rutkowski, Gruder, & Romer, 1983).

Research suggests that the *personality of the helper* also plays a role in helping. Some people are simply more likely to help than others. Consider, for example, the Christians who risked their lives to save Jews from the Nazi Holocaust. Samuel and Pearl Oliner (1988) interviewed more than two hundred of these rescuers and compared their personalities with those of people who had a chance to save Jews but did not do so. The rescuers were found to have more empathy (the ability to understand or experience another's emotional state) (Davis, 1994), more concern about others, a greater sense of responsibility for their own actions, and a greater sense of self-efficacy (confidence in the success of their efforts, as discussed in the chapter on personality). Louis Penner and his associates (Penner & Finkelstein, 1998; Penner, in press) have found that these kinds of personality traits predict a broad spectrum of helping behaviors, ranging from the speed with which bystanders intervene in an emergency to the amount of time volunteers spend helping AIDS victims. Consistent with the arousal: cost-reward theory, these personality characteristics are also correlated with people's estimates of the costs of helping and not helping. For example, empathic individuals usually estimate the costs of not helping as high, and people with a sense of self-efficacy usually rate the costs of helping as low (Penner et al., 1995). These patterns of cost estimation may partially explain why such people tend to be especially helpful.

Other helping-related phenomena cannot be easily explained by the arousal: cost-reward theory. One of these is the impact of *environmental factors* on helping. Research conducted in several countries has revealed, for example, that people in urban areas are generally less helpful than those in rural areas (Aronson, Wilson, & Akert, 2002). Why? It is probably not the simple fact of living in a city but rather the stressors one finds there that tend to make some urban people less helpful. A study conducted in thirty-six North American cities found that people's tendency to

figure 18.8

The Effect of Empathy on Helping

After hearing a staged interview with a woman who supposedly needed to raise money for her family, participants in this experiment were asked to help her. Those who were led to empathize with the woman were much more likely to offer to help her than those who did not empathize with her. These results are consistent with the empathy-altruism theory of helping.

Source: Adapted from Batson et al. (1997).

help was related more strongly to a community's *population density* (the number of people per square mile) than to the overall size of the city in which people lived (Levine et al., 1994). The higher the density, the less likely people were to help others. Similar results have been found in countries such as the United Kingdom, Saudi Arabia, and Sudan (Hedge & Yousif, 1992; Yousif & Korte, 1995). Two explanations have been suggested for this association between environmental stress and reduced likelihood of helping. The first is that stressful environments create bad moods—and generally speaking, people in bad moods are less likely to help (Salovey, Mayer, & Rosenhan, 1991). A second possibility is that noise, crowding, and other urban stressors create too much stimulation. To reduce this excessive stimulation, people may pay less attention to their surroundings, which might include individuals who need help.

It is also difficult for the arousal: cost-reward theory to predict what bystanders will do when the cost of helping and the cost of not helping are *both* high. In these instances, helping (or not helping) may depend on several situational factors and, sometimes, on the personality of the potential helper. There may also be circumstances in which cost considerations may not be the major cause of a decision to help or not help. A second approach to helping considers some of these circumstances.

Empathy-Altruism Theory The second approach to explaining helping is embodied in **empathy-altruism theory**, which maintains that people are more likely to engage in *altruistic*, or unselfish, helping—even when the cost of helping is high—if they feel empathy toward the person in need (Batson, 1998). In one experiment illustrating this phenomenon, C. Daniel Batson had participants listen to a recording of an interview with a female student. The student told the interviewer that her parents had been killed in an automobile accident, that they had no life insurance, and that she was now faced with the task of finishing college while taking care of a younger brother and sister. She said that these financial burdens might force her to quit school or give up her siblings for adoption. None of this was true, but the participants were told that it was. Further, before listening to the woman's story, half the participants were given other information about her that was designed to promote strong empathy. Later, all the participants were asked to help the woman raise money for herself and her siblings (Batson et al., 1997). The critical question was whether the participants who heard the empathy-promoting information would help more than those who did not. Consistent with the empathy-altruism theory, more participants in the empathy condition than in the nonempathy condition offered to help (see Figure 18.8).

Were those who offered help in this experiment being utterly altruistic, or could there be a different reason for their actions? This is a hotly debated question. Some researchers dispute Batson's claim that his study illustrated truly altruistic helping and suggest instead that people help in such situations for more selfish reasons, such as relieving the distress they experienced after hearing of the woman's problems (Cialdini et al., 1997). Although the final verdict on this question is not yet in, the evidence appears to support Batson's contention that empathizing with another person can sometimes lead to unselfish helping (Dovidio, Allen, & Schroeder, 1990).

Evolutionary Theory A third approach to explaining helping is based on the evolutionary approach to social psychology, which views many human social behaviors as echoes of actions that contributed to the survival of our prehistoric ancestors (Burnstein & Brannigan, 2001). At first glance, it might not seem reasonable to apply evolutionary theory to helping and altruism, because helping others at the risk of one's own well-being does not appear adaptive. If we die while trying to save others, it will be their genes, not ours, that will survive. In fact, according to Charles Darwin's concept of the survival of the fittest, helpers—and their genes—should have disappeared long ago. Contemporary evolutionary theorists suggest, however, that Darwin's thinking about natural selection focused too much on the

empathy-altruism theory A theory suggesting that people help others because of empathy with their needs.

Family Ties Research indicates that people are more likely to donate organs to family members than to strangers. This pattern may reflect greater attachment or a stronger sense of social obligation to relatives than to others. However, psychologists who take an evolutionary approach to helping suggest that when, for example, one family member donates a kidney to save the life of another, as in the case of these sisters, the donor is helping to ensure the survival of the genes he or she shares with the recipient.

survival of the fittest *individuals* and not enough on the survival of their genes *in others*. Accordingly, the concept of survival of the fittest has been replaced by the concept of *inclusive fitness*, the survival of one's genes in future generations (Hamilton, 1964). Because we share genes with our relatives, helping or even dying for a cousin, a sibling, or above all, our own child potentially increases the likelihood that at least some of our genetic characteristics will be passed on to the next generation through the beneficiary's future reproduction (Burnstein & Brannigan, 2001). So *kin selection*—helping a relative to survive—may produce genetic benefits for the helper (McAndrew, 2002).

There is considerable evidence that kin selection occurs among birds, squirrels, and other animals. The more closely the animals are related, the more likely they are to risk their lives for one another. Studies in a wide variety of cultures show the same pattern of helping among humans (Buss, 1999). People in the United States are three times as likely to donate a kidney to a relative as to a nonrelative (Borgida, Conner, & Monteufel, 1992), and identical twins (who have exactly the same genes) are much more willing to help one another than are fraternal twins or siblings, who share only 50 percent of their genes (Segal, 1999).

FOCUS ON RESEARCH METHODS

Does Family Matter?

In and of themselves, data on kin selection do not confirm evolutionary theories of helping and altruism. For example, the greater tendency to donate organs to relatives could also be due to the effects of empathy toward more familiar people, pressure from family members, or other social influence processes. To control for the effects of these confounding variables, some researchers have turned to the laboratory to study the role of evolutionary forces in helping behavior.

● What was the researchers' question?

Eugene Burnstein, Christian Crandell, and Shinobu Kitayama (1994) wanted to know whether people faced with a choice of whose life to save would act in a manner consistent with the concept of kin selection. These investigators reasoned that if kin selection does affect helping, the more genetically related two people are—

figure 18.9

Kin Selection and Helping

In this analogue experiment, students said they would be more likely to save the life of a healthy relative than a sick one, but more likely to do a favor for the sick relative. Results like these have been cited in support of evolutionary explanations of helping behavior (Burnstein, Crandell, & Kitayama, 1994).

Source: Burnstein, Crandell, & Kitayama (1994).

the more genes they share in common—the more inclined they should be to save each other's life. However, if the underlying reason for this kind of helping is actually to preserve one's genes in others, the tendency to save a close relative should be lessened if that relative is unlikely to produce offspring and thereby help preserve the helper's genes.

● How did the researchers answer this question?

The most direct way to test these predictions would be to put people's lives in danger and then observe which (if any) of their relatives try to save them. Such an experiment would be unthinkable, of course, so Burnstein and his colleagues used a simulation, or *analogue*, methodology. Specifically, they asked people to imagine a series of situations and then to say how they would respond if the situation were real.

The participants in their analogue experiment were 110 men and 48 women enrolled at universities in Japan and the United States. The first independent variable was the kind of help that was needed. On the basis of random assignment, some participants were asked to imagine life-or-death situations in which there was time to save only one of three people who were asleep in separate rooms of a burning house. The remaining participants were asked to imagine everyday situations in which they had time to help only one of three people who each needed a small favor. The other independent variables were the characteristics of the people needing help in each situation—their age, gender, physical health, and genetic relatedness to the potential helper. The dependent variable was the participants' choice of which person they would help.

● What did the researchers find?

In line with evolutionary theory, the participants were more than twice as likely to say they would save the life of a close relative than that of an unrelated friend. Also, the more closely related the endangered people were to the potential helpers, the more likely they were to be saved. Did these results occur simply because people tend to help closer relatives in any situation? Probably not; when the participants imagined situations in which only small favors were involved, they were only slightly more likely to help a close relative than a distant one.

The other major prediction of evolutionary theory was supported as well. Several different findings indicated that even close relatives might not be saved if they were unlikely to produce offspring. For example, the participants were more willing to do a small favor for a seventy-five-year-old relative than for a ten- or eighteen-year-old relative, but they were much more likely to save the lives of the younger relatives. Similarly, they were more likely to do a favor for a sick relative than for a healthy one; but in a life-or-death situation, they chose to save the healthy relative more often than the sick one (see Figure 18.9). Finally, the participants were more likely to save the life of a female relative than that of a male relative, unless the female was past childbearing age. There were no substantial differences between the responses of students in the United States and those in Japan.

● What do the results mean?

The results of this experiment generally support the concept of kin selection, which says that we are inclined to help close relatives because in the long run it helps us. Specifically, if we save the life of a relative and that relative is able to produce offspring, we have really helped ourselves, because more of our genes will be represented in the next generation. Evolutionary psychologists see these results as providing confirmation that kin selection affects the decisions people make about saving the life of another person, and thus that there is an evolutionary basis for helping.

● What do we still need to know?

The findings reported by Burnstein and his colleagues are consistent with the predictions of evolutionary theory, but they must be interpreted with caution and in

light of the methods that were used to obtain them. Analogue studies give clues to behavior—and allow experimental control—in situations that approximate, but may not precisely duplicate, situations outside the laboratory. These studies tend to be used when it would be unethical or impractical to expose people to “the real thing.” The more closely the analogue approximates the natural situation, the more confident we can be that conclusions drawn about behavior observed in the laboratory will apply, or generalize, to the world beyond the laboratory.

In an analogue experiment such as this one, we might question how closely the natural situation was approximated. For one thing, the participants predicted what their responses would be in hypothetical situations. Those responses might be different if the students were actually in the situations described. So although the analogue methodology in this study allowed the researchers to show that kin selection *could* play a role in human helping behavior; they did not demonstrate that it *did* play a role.

The study also failed to identify the mechanisms whereby biological tendencies are translated into thoughts that lead to helpful actions (Batson, 1998). It is highly unlikely that the participants were thinking, “I’ll help a close relative because it will preserve my genes.” So what conscious thoughts or feelings led to their choices? A recent analogue study by Josephine Korchmaros and David Kenny (2001) provides a partial answer to this question. In their simulation, the names of the people who needed help were those of the participants’ actual family members. Further, the researchers measured the strength of the *emotional ties* between the participants and these particular people. The results suggested that genetic closeness was related to emotional closeness. Perhaps, then, emotional closeness provides the mechanism that drives the choice of whom to help. It may be that we are biologically predisposed to feel emotionally closer to closer relatives and thus more likely to help them if their lives are in danger. These feelings, in turn, serve to increase the chances that some of our genes will survive in those close relatives.

This is a reasonable possibility, but remember that even though evolutionary theory may explain some general human tendencies to help, it cannot predict the behavior of specific individuals in specific situations (Batson, 1998). Like all behavior, helping and altruism depend on the interplay of many genetic and environmental factors—including interactions between particular people and particular situations. (See “In Review: Theories of Helping Behaviors” for a summary of the major reasons why people help and the conditions under which they are most likely to do so.)

in review

Theories of Helping Behaviors

Theory	Basic Premise	Important Variables
Arousal: cost-reward	People help in order to reduce the unpleasant arousal caused by another person’s distress. They attempt to minimize the costs of doing this.	Factors that affect the costs of helping and of not helping.
Empathy-altruism	People sometimes help for utterly altruistic reasons. They are motivated by a desire to increase another person’s well-being.	The amount of empathy that one person feels for another.
Evolutionary	People help relatives because it increases the chances that the helper’s genes will survive in future generations.	The biological relationship between the helper and the recipient of help.

Cooperation, Competition, and Conflict

When people interact with one another while attempting to reach some goal, three kinds of behavior can result: cooperation, competition, or conflict. **Cooperation** is any type of behavior in which people work together to attain a goal. For example, several law students might form a study group to help one another pass a difficult exam. People can also engage in **competition**, trying to attain a goal for themselves while denying that goal to others. So those same students might later compete with one another for a single job opening at a prestigious law firm. Finally, **conflict** results when one person or group believes that another stands in the way of their achieving a goal. When the students become attorneys and represent opposing parties in a legal dispute, they will be in conflict. One way in which psychologists have learned about all three of these behaviors is by studying social dilemmas (Gifford & Hine, 1997b).

Social Dilemmas

Social dilemmas are situations in which an action that produces rewards for one individual will, if adopted by all others, produce negative consequences for everyone (Dawes & Messick, 2000). For instance, it might be in a factory owner's short-term self-interest to save the costs of pollution control by releasing untreated toxic waste; but if all factories do the same, the air and water will eventually become poisonous for everyone. One particular kind of social dilemma that psychologists have studied extensively is called the two-person "prisoner's dilemma."

The Prisoner's Dilemma The prisoner's dilemma is based on a scenario in which two people are separated immediately after being arrested for a serious crime (Taylor, Peplau, & Sears, 2000). The district attorney believes they are guilty but does not have the evidence to convict them. Each prisoner can either confess or not. If they both refuse to confess, each will be convicted of a minor offense and will be jailed for one year. If they both confess, the district attorney will recommend a five-year sentence. However, if one prisoner remains silent and one confesses, the district attorney will allow the confessing prisoner to go free, whereas the other will serve the maximum ten-year sentence.

Cooperation, Competition, Conflict, and Cash Cooperation, competition, and conflict can all be seen on *Survivor*, a television series in which people try to win a million dollars by staying the longest in some remote location. Early on, contestants cooperate with members of their own teams, but as more and more people are eliminated, even team members compete with one another. When only two people remain, each stands in the way of the other's goal of winning, so they are in direct conflict.

A Social Dilemma If everyone in North America used public transportation or commuted in carpools, and if they drove small cars with fuel-efficient engines that minimized exhaust emissions, the problems of air pollution, traffic and parking, and highway construction and maintenance would be greatly reduced. However, most people like to drive to work alone, at the wheel of a car that is fun to drive and be seen in, but that may guzzle gas and take up a lot of space. In short, the choice of daily transportation reflects a social dilemma; what is good for the individual in the short run is bad for society in the long run.

Each prisoner faces a dilemma. Figure 18.10(A) outlines the possible outcomes. Obviously, the strategy that will guarantee the best *mutual* outcome—short sentences for both prisoners—is cooperation: Both should remain silent. But the prisoner who remains silent runs the risk of receiving a long sentence if the other prisoner confesses, and the prisoner who confesses has the chance of gaining individually if the other prisoner does not talk. In other words, each prisoner has an incentive to compete for freedom by confessing. But if they both compete and confess, each will end up going to jail for longer than if nothing was said.

In the typical prisoner's dilemma experiment, two people sit at separate control panels. Each of them has a red button and a black button, one of which is to be pushed on each of many trials. Pressing the black button is a cooperative response; pressing the red button is a competitive response. For example, if, on a given trial, both participants press their black buttons, each wins \$5. If both press their red buttons, they earn only \$1. However, if one player presses the red button and the other presses the black button, the one who pressed the red button will win \$10, and the other will win nothing.

Figure 18.10(B) shows the possible outcomes for each trial. Over the course of the experiment, the combined winnings of the players are greatest if each presses the black button—that is, if they cooperate. By pressing the black button, however, a player becomes open to exploitation, because on any trial the other might press the red button and take all the winnings. So each player stands to benefit the most individually by pressing the red button occasionally. The prisoner's dilemma is what psychologists call a *mixed-motive conflict*—there are good reasons to cooperate and also good reasons to compete.

What happens when people play this game? Overall, there is a strong tendency to respond competitively; people find it difficult to resist the competitive choice on any given trial (Komorita & Parks, 1995). This choice wins them more money on that trial, but in the long run they gain less than they would have gained through cooperation.

cooperation Any type of behavior in which people work together to attain a goal.

competition Behavior in which individuals try to attain a goal for themselves while denying that goal to others.

conflict The result of a person's or group's belief that another person or group stands in the way of their achieving a valued goal.

social dilemmas Situations in which actions that produce rewards for one individual will produce negative consequences if adopted by everyone.

prisoner's dilemma A social dilemma in which mutual cooperation guarantees the best mutual outcome.

		Prisoner A	
		Does not confess	Confesses
Prisoner B	Does not confess	1 year / 1 year	Released / 10 years
	Confesses	10 years / Released	5 years / 5 years

The Prisoner's Dilemma

In the prisoner's dilemma, mutual cooperation benefits each person, and mutual competition is harmful to both, but one party can exploit the cooperativeness of the other. These diagrams show the potential payoffs for prisoners—and research participants—in prisoner's dilemma studies.

If acting competitively leads to smaller rewards in the long run, why do people persist in competing? There seem to be two reasons (Komorita, 1984). First, winning more than an opponent seems to be rewarding in itself. In the prisoner's dilemma game, many people want to outscore an opponent even if the result is that they win less money overall. Second, and more important, once several competitive responses are made, the competition seems to feed on itself (Insko et al., 1990). Each person becomes distrustful of the other, and cooperation becomes increasingly difficult. The more competitive one person acts, the more competitive the other becomes (McClintock & Liebrand, 1988).

Resource Dilemmas In recent years, psychologists interested in cooperation, competition, and conflict have concentrated on another kind of social dilemma, called a *resource dilemma* (Pruitt, 1998). In a **resource dilemma**, people share some common resource, thus creating inherent conflicts between the interests of the individual and those of the group, and also between people's short-term and long-term interests (Schroeder, 1995). There are two kinds of resource dilemmas. In the *commons dilemma*, people have to decide how much to take from a common resource; in the *public goods dilemma*, people must decide how much to contribute to a common resource. As an example of the commons dilemma, consider a situation in which farmers all draw water for their crops from the same lake. Each individual farmer would benefit greatly from unrestricted use of the water, but if all the farmers did the same, the water would soon be gone. Tax laws provide an example of the public goods dilemma. In the short run, you would benefit greatly if you did not pay taxes, but if everyone failed to pay, no one would have police and fire protection, highway repairs, national defense, or other vital government services. How can people facing such dilemmas be prompted to cooperate?

Fostering Cooperation

Communication can reduce people's tendency to act competitively (Pruitt, 1998). Unfortunately, however, not all communication increases cooperation, just as not all contact between ethnic groups reduces prejudice. If the communication takes the form of a threat, people apparently interpret the threat itself as a competitive response and are likely to respond competitively (Gifford & Hine, 1997b). Furthermore, the communication must be relevant. In one social dilemma study, cooperation increased only when people spoke openly about the dilemma and how they would be rewarded for various responses. Praising one another for past cooperation was most beneficial (Orbell, van de Kragt, & Dawes, 1988).

People can also communicate implicitly through the strategy they use. In the prisoner's dilemma, the most effective strategy for producing long-term cooperation is to use basic learning principles and play *tit-for-tat*, rewarding cooperative responses with cooperation and punishing exploitation with exploitative strategies of one's own. Cooperating after a cooperative response and competing after a competitive response produces a high degree of cooperation over time (Nowak, May, & Sigmund, 1995). Apparently, the players learn that the only way to come out ahead is to cooperate. There is even evidence from computer simulation studies that societies whose members use cooperative strategies with one another are more likely to survive and prosper than are societies whose members act competitively (Nowak, May, & Sigmund, 1995).

Interpersonal Conflict

In social dilemmas and other situations in which people are *interdependent*—that is, when what one person does always affects the other—cooperation usually leads to the best outcomes for everyone. This doesn't mean, however, that cooperation always occurs. People from collectivist cultures, in which cooperation is empha-

resource dilemma A situation in which people must share a common resource, creating conflicts between the short-term interests of individuals and the long-term interests of the group.

"There's quite a power struggle going on."

sized, are generally less likely to act selfishly in a social dilemma, but conflict in such situations does appear in all cultures (Smith & Bond, 1999). Conflict is especially likely when people are involved in a **zero-sum game**. This is a situation in which one person's gains are subtracted from the other person's resources; the sum of the gains and losses is zero. Election campaigns, lawsuits over a deceased relative's estate, and competition between children for a coveted toy are all examples of zero-sum games.

There are four major causes of interpersonal conflict (Baron & Byrne, 1994). One is *competition for scarce resources*. If a business has only five offices with windows, for example, employees will compete for them. Some managers report spending as much as 20 percent of their time dealing with interpersonal conflicts based on such competition (Thomas & Schmidt, 1976). A second major cause of interpersonal conflict is *revenge*. People reciprocate not only positive actions but also negative ones. Some people who feel exploited, deprived, or otherwise aggrieved spend months, or even years, plotting ways of getting back at those they hold responsible (Baron & Richardson, 1994).

Interpersonal conflict may also arise because people *attribute unfriendly or selfish motives to others* (Gifford & Hine, 1997a). For example, conflict is likely to emerge if people who must share some resource, such as printer paper, attribute a shortage of that resource to the other people's selfishness rather than to factors over which they have no control, such as an inadequate supply (Samuelson & Messick, 1995). Sometimes these attributions are accurate, but often conflict results from the kinds of attributional errors discussed in the chapter on social cognition.

Attributional errors are related to a final source of interpersonal conflict: *faulty communication*. A comment intended as a compliment is sometimes interpreted as a snide remark; constructive criticism is sometimes perceived as a personal attack. Such miscommunication may start a cycle of increasingly provocative actions, in which each person believes the other is being aggressive and unfair (Pruitt & Carnevale, 1993).

Managing Conflict Interpersonal conflict can damage relationships among people and impair the effectiveness of organizations, but it can also lead to beneficial changes. Industrial/organizational psychologists have found that often it is much better to manage conflict effectively than to try to eliminate it. The most common way of managing organizational conflict is through *bargaining*. Each side—labor and management, for example—produces a series of offers and counteroffers until a solution that is acceptable to both sides emerges. At its best, bargaining can produce a win-win situation in which each side receives what is most important and gives up what is less important (Carnevale & Pruitt, 1992).

If bargaining fails, *third-party interventions* may be useful. Like a therapist working with a couple, an outside mediator can often help the two sides in an organizational conflict focus on important issues, defuse emotions, clarify positions and proposals, and make suggestions that allow each side to compromise without losing face (Pruitt, 1998).

Other techniques for managing conflict, especially conflict over resources, involve the introduction of *superordinate goals* or a *superordinate identity* (Williams, Jackson, & Karau, 1995). For example, if people who are competing for scarce resources can be made to feel that they are all part of the same group and share the same goals, they will act less selfishly and manage the limited resources more efficiently. Focusing on larger common goals was part of what created the unprecedented level of cooperation among people all over the United States following the September 11, 2001, terrorist attacks on New York City and Washington, D.C.

In short, although interpersonal conflict can be harmful if left unchecked, it can also be managed in a way that benefits the group. Much as psychotherapy can help people resolve personal conflict in a way that leads to growth, interpersonal conflict within an organization can be handled in a way that leads to innovations, increased loyalty and motivation, and other valuable changes.

zero-sum game A social situation in which one person's gains are subtracted from another person's resources, so that the sum of the gains and losses is zero.

Group Processes

Although Western industrialized cultures tend to emphasize individuals over groups, the fact remains that most important governmental and business decisions in those cultures and elsewhere are made by groups, not individuals (Cannon-Bowers & Salas, 1998). Sometimes group processes are effective, as when a team of doctors, nurses, specialists, and two parents brought the McCaughey septuplets into the world on November 19, 1997. At other times, group processes can have disastrous results, as we will see later. In the chapter on cognition and language, we describe some of the factors that influence the nature and quality of group decisions. Here, we consider some of the social psychological processes that often occur in groups to alter the behavior of their members and the quality of their collective efforts.

Group Leadership

A good leader can help a group pursue its goals; a poor one can impede a group's functioning. What makes a good leader? Early research suggested that the personalities of good and bad leaders were about the same, but we now know that certain personality traits often distinguish effective from ineffective leaders. For example, using tests similar to those that measure the big-five traits described in the chapter on personality, Colin Silverthorne (2001) examined the characteristics of leaders in the United States, Thailand, and China. He found that effective leaders in all three countries tended to score high on agreeableness, emotional stability, extraversion, and conscientiousness. Other researchers have found that in general, effective leaders are intelligent, success oriented, and flexible (Levine & Moreland, 1998).

Having particular personality traits does not guarantee good leadership ability, however. People who are effective leaders in one situation may be ineffective in another (Yukl & Van Fleet, 1992). The reason is that effective leadership also depends on the characteristics of the group members, the task at hand, and most important, the interaction between these factors and the leader's style.

Two main styles of leadership have been identified. **Task-oriented leaders** provide close supervision, lead by giving directives, and generally discourage group discussion (Yukl & Van Fleet, 1992). Their style may not endear them to group members. In contrast, **person-oriented leaders** provide loose supervision, ask for group members' ideas, and are generally concerned with subordinates' feelings. They are usually well liked by the group, even when they must reprimand someone (Taylor, Peplau, & Sears, 2000).

Research on leadership effectiveness and gender provides one explanation as to why one leadership style is not invariably better than another. According to Alice Eagly and her associates, men and women in Western cultures tend to have different leadership styles (Eagly & Johnson, 1990; Eagly, Karau, & Makhijani, 1995). Men tend to be more task oriented; women, more person oriented. One interpretation of these differences is that the gender-role learning processes described in the chapter on human development lead men and women to "specialize" in different leadership behaviors.

Overall, men and women are equally capable leaders, but men tend to be more effective when success requires a more task-oriented leader, and women tend to be more effective when success requires a more person-oriented leader. In other words, people of each gender tend to be most effective when they are acting in a manner consistent with gender-role traditions (Eagly & Karau, 1991; Eagly, Karau, & Makhijani, 1995). This may be one reason some people do not like female leaders who act in a "masculine" manner or occupy leadership positions traditionally held by men (Eagly, Makhijani, & Klonsky, 1992). In certain circumstances, such responses create bias against women leaders, particularly among male members of the groups they lead (Eagly, Makhijani, & Klonsky, 1992).

task-oriented leaders Leaders who provide close supervision, lead by directives, and generally discourage group discussion.

person-oriented leaders Leaders who provide loose supervision, ask for group members' ideas, and are concerned with subordinates' feelings.

A Team Effort How many people does it take to deliver a baby? Multiply your answer by seven, and you still won't come close to the number of medical professionals who, in 1997, worked as a well-organized team to ensure the healthy delivery of the McCaughey septuplets.

Most contemporary theories of leadership are known as *contingency theories* (Levine & Moreland, 1998) because they suggest that leadership effectiveness is contingent, or depends, on factors such as the leader's relations with group members and the nature of the group's task. They note, for example, that task-oriented leaders tend to be most effective when the group is working under time pressure, when the task is unstructured, and when circumstances make it unclear as to what needs to be done first and how the duties should be divided. People trapped in an elevator in a burning building, for example, need a task-oriented leader. Conversely, person-oriented leaders tend to be most effective when the task is structured and there are no severe time limitations (Chemers, 1987). These people would be particularly successful, for example, in managing an office in which the workers knew their jobs well.

Groupthink

The emphasis on group decisions in most large organizations is based on the belief that a group of people working together will make better decisions than will individuals working alone. As noted in the chapter on cognition and language, this belief is generally correct; yet under certain circumstances, groups have been known to make amazingly bad decisions (Levine & Moreland, 1998). Consider an example from 1986, when officials at the National Aeronautics and Space Administration (NASA) ignored engineers' warnings about the effects of cold weather and decided to launch the space shuttle *Challenger*. The spacecraft exploded seventy-three seconds after liftoff, killing everyone aboard. After analyzing disastrous decisions such as this one, Irving Janis (1989) proposed that they can be attributed to a phenomenon called **groupthink**. Groupthink occurs, he said, when group members are unable to realistically evaluate the options available to them or to fully consider the potential negative consequences of a contemplated decision. It is particularly likely when members of a group place a higher value on reaching a consensus than on being sure they have made the right decision.

Trying to reach a consensus before a group acts is not necessarily a bad strategy. In fact, it usually produces a good decision and positive feelings about the group (Smith & Mackie, 2000). But the drive toward consensus is likely to produce groupthink and bad decisions when four conditions are present: (1) the consensus is not based on all the facts at hand, (2) group members all share certain biases, (3) members who express dissenting opinions are punished or even ejected from the group, and (4) the group leader puts pressure on the members to reach consensus (Ahlfinger & Esser, 2001; Smith & Mackie, 2000). This last condition appeared to play a crucial role in the U.S. government's decision to support a disastrously unsuccessful invasion of Cuba by anti-Castro Cubans in 1961. Before the final decision

LINKAGES (a link to Health, Stress, and Coping)

groupthink A pattern of thinking in which group members fail to evaluate realistically the wisdom of various options and decisions.

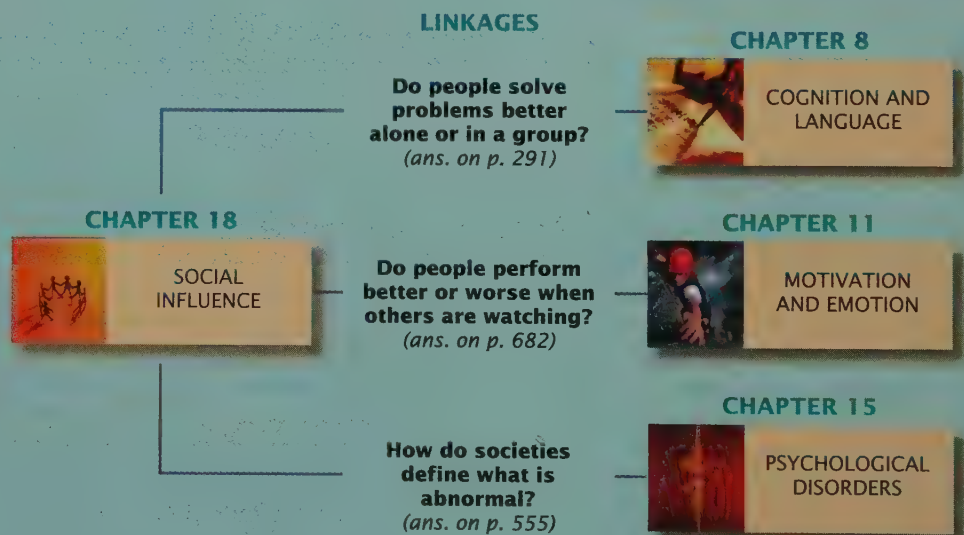

was made, several advisers were told that President John F. Kennedy had made up his mind to support the invasion and that it was time to “close ranks with the president.” This situation created enormous pressure for conformity (McCauley, 1989).

Some researchers have questioned the prevalence and dangers of groupthink (e.g., Aldag & Fuller, 1993; Park, 2000). Most researchers agree that groupthink does occur, though, and many of them have worked on developing techniques to help groups avoid it.

One way to avoid groupthink is to designate someone to take the unpopular role of “devil’s advocate”—to constantly challenge the group’s emerging consensus and offer additional alternatives. This person forces the group to consider all the facts and every possible decision option (Janis, 1985; Risen, 1998). Another technique is to encourage the expression of diverse opinions by allowing them to be presented anonymously. The group members might sit at separate computers and type out messages about all the options that occur to them. Each message is displayed for all to see on an electronic mail system that protects each sender’s identity. This procedure allows the group to discuss the options via e-mail without knowing who is saying what. Research on this technique suggests that it is effective in stimulating logical debate and making people less inhibited about disagreeing with the group (O’Brien, 1991).

LINKAGES

As noted in the chapter on introducing psychology, all of psychology’s subfields are related to one another. Our discussion of how the presence of other people affects a person’s motivation to perform illustrates just one way in which the topic of this chapter, social influence, is linked to the subfield of motivation and emotion (see the chapter on that topic). The Linkages diagram shows ties to two other subfields as well, and there are many more ties throughout the book. Looking for linkages among subfields will help you see how they all fit together and help you better appreciate the big picture that is psychology.

SUMMARY

Social Influence

Norms establish the rules for what should and should not be done in a particular situation. Descriptive norms indicate what most other people do and create pressure to do the same. Injunctive norms provide specific information about what others approve or disapprove of. *Deindividuation* is a psychological state in which people temporarily lose their individuality, their normal inhibitions are relaxed, and they may perform aggressive or illegal acts that they would not do otherwise.

Social facilitation, *social impairment*, and *social loafing* provide three other examples of how the presence of other people can affect an individual’s behavior.

Conformity and Compliance

When behavior or beliefs change as the result of unspoken or implicit group pressure, *conformity* has occurred; when the change is the result of a request, *compliance* has occurred.

The Role of Norms

People tend to follow the normative responses of others, and groups create norms when none already exist.

Why Do People Conform?

People sometimes exhibit public conformity without private acceptance; at other times, the responses of other people have a genuine impact on private beliefs. People conform because they want to be right, because they want to be liked, and because they tend to be rewarded for doing so.

When Do People Conform?

People are most likely to conform when the situation is ambiguous, as well as when others in the group are in unanimous agreement. Up to a point, conformity usually increases as the number of people holding the majority view grows larger. Persistent and unanimous *minority influence* can also produce some conformity.

Inducing Compliance

Effective strategies for inducing compliance include the foot-in-the-door technique, the door-in-the-face procedure, and the low-ball approach.

Obedience

Obedience involves complying with an explicit demand, typically from an authority figure. Research by Stanley Milgram indicates that levels of obedience are high even when obeying an authority appears to result in pain and suffering for another person.

Factors Affecting Obedience

People obey someone who has certain kinds of social power. Obedience declines when the status of the authority figure declines, as well as when others are observed to disobey. Some people may be more likely to obey orders than others.

Evaluating Milgram's Studies

Because participants in Milgram's studies experienced considerable stress, the experiments have been questioned on ethical grounds. Nevertheless, Milgram's research showed that even apparently "normal" people can be influenced to inflict pain on others.

Aggression

Aggression is an act intended to harm another person.

Why Are People Aggressive?

Sigmund Freud saw aggression as due partly to self-destructive instincts. More recent theories attribute aggressive tendencies to genetic factors, brain dysfunctions, and hormonal influences. Learning is also important; people learn to display aggression by watching others and by being rewarded for aggressive behavior. There are wide cultural differences in the incidence of aggression.

When Are People Aggressive?

A variety of emotional factors play a role in aggression. The *frustration-aggression hypothesis* suggests that frustration can lead to aggression, particularly if cues that invite or promote aggression are present. Recent research indicates that stress and negative feelings play a major role in aggression. Arousal from sources unrelated to aggression, such as exercise, can also make aggressive responses more likely, especially if aggression is already a dominant response in that situation. Research in *environmental psychology* suggests that factors such as high temperature, air pollution, noise, and crowding increase the likelihood of aggressive behavior, particularly among people who are already angry.

Altruism and Helping Behavior

Human behavior is also characterized by *helping behavior* and *altruism*.

Why Do People Help?

There are three major theories of why people help others. According to the *arousal: cost-reward theory*, people help in order to reduce the unpleasant arousal they experience when others are in distress. Their specific reaction to a suffering person depends on the costs associated with helping or not helping. Helping behavior is most likely when the costs of helping are low and the costs of not helping are high. Perceptions of cost are affected by the clarity of the need for help, diffusion of responsibility, and personality traits. Environmental factors also affect willingness to help. The *empathy-altruism theory* suggests that helping can be truly unselfish if the helper feels empathy for the person in need. Evolutionary theory suggests that humans have an innate tendency to help others, especially relatives, because doing so increases the likelihood that family genes will survive.

Cooperation, Competition, and Conflict

Cooperation is behavior in which people work together to attain a goal; *competition* exists when individuals try to attain a goal while denying that goal to others; *conflict* occurs when a person or group believes that someone stands in the way of something of value.

Social Dilemmas

In *social dilemmas*, selfish behavior that benefits individuals in the short run may spell disaster in the long run if adopted by an entire group. Two kinds of social dilemmas are the *prisoner's dilemma* and *resource dilemmas*. When given a choice between cooperation and competition in a social dilemma, people often compete with one another. This is true even though they may receive fewer rewards for competing than for cooperating.

Fostering Cooperation

Communication between competing parties can increase cooperation, especially if the communication is nonthreatening and relevant to the situation. One of the most effective strategies for producing long-term cooperation in a prisoner's dilemma is

rewarding cooperative responses with cooperation and punishing exploitation by using exploitative strategies of one's own.

Interpersonal Conflict

In *zero-sum games*, competition is almost inevitable, because there can be only one winner. Competition for scarce resources, revenge, attribution of another's behavior to unfriendly motives, and faulty communication are frequent sources of interpersonal conflict. Bargaining, third-party interventions, and reminders about broader goals and shared identity are helpful procedures for managing conflict.

Group Processes

Many of the world's most important decisions are made by groups.

Group Leadership

No single personality type or behavioral style always results in good leadership. *Task-oriented leaders* are most effective when the task is unstructured and the group is working under time pressure. *Person-oriented leaders* are most effective when the task is structured and there are no severe time limitations. Contingency theories of leadership effectiveness propose that success depends on the extent to which a leader's style fits the characteristics of the group and its tasks.

Groupthink

The pattern of thinking called *groupthink* occurs when the desire to reach a consensus becomes more important than the need to reach the best decision.

Behavioral Genetics

Think about some trait on which you are well above or well below average. Perhaps it relates to your skill at sports, languages, or music, or maybe to your fearfulness, sociability, or other aspects of personality. Have you ever wondered what made you the way you are? If you are shy, for example, it is easy to think of possible environmental explanations. Perhaps you are shy because as a child you had few opportunities to meet new children or because you had embarrassing or unpleasant experiences when you did meet them. Maybe you have shy parents who served as the role models you imitated. Such environmental explanations are certainly reasonable, but it is also possible that you inherited a disposition toward shyness from your parents.

Topics such as these are addressed by researchers in the field of *behavioral genetics*, the study of how genes affect behavior (see the chapter on research in psychology). These researchers have developed methods to explore genetic, as well as environmental, origins of behavioral differences among people. The results of behavioral genetics research make it clear that heredity has a surprisingly strong influence, not just on shyness but on personality more generally, on cognitive abilities, on psychological disorders, and on many other aspects of human behavior and mental processes. However, behavioral genetics is just as much the study of environment as of genetics. In the process of trying to disentangle genetic from environmental factors, researchers have made several important discoveries about the impact of the environment.

In this appendix, we discuss behavioral genetics in more detail than in the chapter on research in psychology. We begin with a review of the biochemical mechanisms underlying genetics and heredity. We then offer a brief history of genetic research in psychology, followed by a discussion of what research on genetic influences can and cannot tell us about the origins of human differences. Finally, we describe some findings from behavioral genetics research that illuminate several important aspects of human behavior and mental processes.

The Biology of Genetics and Heredity

What does it mean to say that someone has genetically inherited some physical feature or behavioral trait? The answer lies in **genetics**, the biology of inheritance. The story begins with the chemistry of the human body and with the chromosomes contained within each of the body's cells. Most human cells contain forty-six chromosomes, arranged in twenty-three matching pairs. These **chromosomes** are long, thin structures that are made up of thousands of genes. **Genes** are the biochemical units of heredity that govern the development of an individual by controlling the synthesis of protein. They are composed of **deoxyribonucleic acid (DNA)**—strands of sugar, phosphate, and four kinds of nitrogen-containing molecules twisted around each other in a double spiral (see Figure 1). It is the particular order in which the four nitrogen-containing molecules are arranged in the DNA that determines, through the production of **ribonucleic acid (RNA)**, which protein each gene will produce. Protein molecules, in turn, form the physical structure of each cell and also direct the activity of the cell. So as a function of DNA, the genes contain a coded message that provides a blueprint for constructing every aspect of a physical human being, including eye color, height, blood type, inherited disorders, and the like—and all in less space than the period that ends this sentence.

New cells are constantly being produced by the division of existing cells. Most of the body's cells divide through a process called *mitosis*, in which the cell's

genetics The biology of inheritance.

chromosomes Long, thin structures in every biological cell that contain genetic information.

genes The biological instructions, inherited from both parents and located on the chromosomes, that provide the blueprint for physical development.

deoxyribonucleic acid (DNA) The molecular structure of a gene that provides the genetic code.

figure 1
Genetic Building Blocks

Only about 3 percent of DNA contains genes that guide the production of proteins, but it nevertheless determines all aspects of our physical bodies, and influences many of our behavioral characteristics, too.

"Genetic Building Blocks" from *Time*, January 17, 1994. Copyright © 1994 TIME, Inc. Reprinted with permission.

chromosomes duplicate themselves so that each new cell contains copies of the twenty-three pairs of chromosomes in the original.

A different kind of cell division occurs when a male's sperm cells and a female's egg cells (called *ova*) are formed. This process is called *meiosis*. In meiosis, the chromosome pairs are not copied. Instead, they are randomly split and rearranged, leaving each new sperm and egg cell with just one member of each chromosome pair, or twenty-three single chromosomes. No two of these special new cells are quite the same, and none contains an exact copy of the person who produced it. So at conception, when a male's sperm cell *fertilizes* the female's ovum, a truly new cell is formed. This fertilized cell, called a *zygote*, carries twenty-three pairs of chromosomes—half of each pair from the mother and half from the father. The zygote represents a unique heritage, a complete genetic code for a new person that combines genes from both parents. As described in the chapter on human development, the zygote divides first into copies of itself and then into the billions of specialized cells that form a new human being.

Whether or not genes express themselves in the individual who carries them depends on whether they are dominant or recessive. *Dominant* genes are outwardly expressed whenever they are present; *recessive* genes are expressed only when they are paired with a similar gene from the other parent. For example, phenylketonuria (PKU)—a disorder seen in about 1 in 10,000 newborns—is caused by a recessive gene. When inherited from both parents, this gene disrupts the body's ability to control phenylalanine, an amino acid found in milk and other foods. As a result, this acid is converted into a toxic substance that can cause severe mental retardation. (Discovery of this genetic defect made it possible to prevent retardation in children with PKU simply by making sure they did not consume foods high in phenylalanine.) PKU is one of more than 4,000 single-gene disorders, but in fact, relatively few human characteristics are controlled by just one gene. Most characteristics are **polygenic**, meaning that they are controlled by many genes. Even a person's eye color and height are affected by more than one gene.

The genes contained in the forty-six chromosomes inherited from parents make up an individual's **genotype**. Because identical twins develop from one fertilized egg cell, they are described as *monozygotic*; they have exactly the same genotype. So, why don't all identical twins look exactly alike? Because they do not have the same environment. An individual's **phenotype** is the set of observable characteristics that result from the interaction of heredity and environment. In twins and nontwins alike, the way people actually look and act is influenced by the combination of genes they carry, as well as by environmental factors—in other words, by both nature and nurture.

polygenic A term describing characteristics that are determined by more than one gene.

genotype The full set of genes, inherited from both parents, contained in twenty-three pairs of chromosomes.

phenotype How an individual looks and acts, which depends on how inherited characteristics interact with the environment.

A Brief History of Genetic Research in Psychology

The field now known as behavioral genetics began in the late 1800s with the work of Sir Francis Galton. A cousin of Charles Darwin, Galton was so impressed with Darwin's book on evolution that he decided to study heredity in the human species, especially as it related to human behavior. Galton suggested the family, twin, and adoption study designs that are the mainstays of human behavioral genetics research today (see the chapter on research in psychology). He even coined the phrase *nature-nurture* to refer to genetic and environmental influences. Galton's most famous behavioral genetics study was one in which he showed that genius runs in families. Unfortunately, Galton went too far in interpreting the evidence from this family study when he concluded that "nature prevails enormously over nurture" (Galton, 1883, p. 241). As noted in the chapter on research in psychology, family similarity can be due to environmental, as well as hereditary, factors. Still, Galton's work helped to stimulate psychologists' interest in the influence of genetics. The first twin and adoption studies were conducted in 1924. Both focused on IQ, and both suggested the existence of an important genetic contribution to intelligence.

However, research on the influence of genetics on behavior and mental processes was inhibited for a while because of two factors. The first was the impact of John B. Watson's behaviorism, which, as mentioned in the introductory chapter, suggested that we are what we learn. In 1925, Watson insisted "that there is no such thing as an inheritance of capacity, talent, temperament, mental constitution and characteristics. These things again depend on training that goes on mainly in the cradle" (Watson, 1925, pp. 74–75). The second factor discouraging attention to human genetics was its association with the view proclaimed by Adolf Hitler and his Nazis that certain groups of people were "genetically inferior." This view led to the Holocaust during World War II, a campaign of genocide during which millions of Jews and other allegedly "inferior" people were killed.

Genetic research on human behavior was reduced to a trickle during the 1930s and 1940s, but research with animals led, in 1960, to publication of the first behavioral genetics textbook (Fuller & Thompson, 1960) and to signs of increased interest in human genetics. In 1963 an influential article reviewed family, twin, and adoption findings and concluded that genetic factors are an important influence on IQ (Erlenmeyer-Kimling & Jarvik, 1963). Around the same time, the first adoption study of schizophrenia pointed to a strong genetic contribution to that disorder (Heston, 1966).

In the early 1970s, however, interest in human behavioral genetics among psychologists faded again, this time because of reactions to two publications. The first was a paper by Arthur Jensen suggesting that differences in average IQ between blacks and whites might be partly due to genetic factors (Jensen, 1969). The second was a book by Richard Herrnstein in which he argued that genetics might contribute to social class differences (Herrnstein, 1973). The furious public and scientific response to these publications—which included branding the authors as racists—inhibited genetic research in psychology, even though very few behavioral geneticists were studying ethnic or class differences. It was not until later in the 1970s and into the 1980s that major genetic studies were again conducted in psychology.

Today most psychologists recognize the role of both genetics and environment in behavior and mental processes, including the controversial area of cognitive abilities (Snyderman & Rothman, 1987). In fact, in 1992 the American Psychological Association selected behavioral genetics as one of two themes best representing the past, present, and especially the future of psychological research (Plomin & McClearn, 1993). To some, though, the study of human behavioral genetics still carries a hint of racism and class elitism. These concerns were resurrected nearly a decade ago by a book titled *The Bell Curve*, which considers the role of genetics in

ethnic differences in intelligence and the implications of intelligence for social class structure (Herrnstein & Murray, 1994). Fortunately, reaction to that book has not altered the balanced perspective that recognizes the importance of nature as well as nurture in psychology (Neisser, 1997; Pinker, 2002).

The Focus of Research in Behavioral Genetics

Much of the controversy about behavioral genetics, and about nature and nurture in general, comes from misunderstandings about what behavioral genetics researchers study and, more specifically, what it means to say that genes influence behavior.

For one thing, behavioral genetics is the study of genetic and environmental factors responsible for *differences* among individuals or groups of individuals, not for the characteristics of a single individual. Consider height, for example. Identical twins are much more similar in height than are fraternal twins (who share no more genes than other siblings), and individuals who are genetically related but raised separately are just as similar in height as are relatives reared together. Further, genetically unrelated individuals reared together are no more similar in height than random pairs of individuals. These data suggest, not surprisingly, that height is highly *heritable*. This means that much of the *variability* in height that we see among people—actually about 80 percent of it—can be explained by genetic differences among them rather than by environmental differences. (It does not mean that a person who is six feet tall grew 80 percent of that height because of genes and the other 20 percent because of environment!) It also follows that if a person is, say, shorter than average, genetic reasons are probably the primary cause. We say “probably” because finding a genetic influence on height involves referring only to the origins of average individual differences in the population. So although the difference in people’s heights is attributable mainly to genetic factors, a particular person’s height could be due mainly to an early illness or other growth-stunting environmental factors.

To see how this logic applies to conclusions about psychological characteristics, suppose a researcher found that the heritability of a personality trait is 50 percent. This result would mean that approximately half of the differences among people on that trait are attributable to genetic factors. It would not mean that each person inherits half of the trait and gets the other half from environmental influences. As in our height example, behavioral geneticists want to know how much variability among people can be accounted for by genetic and environmental factors. The results of their research allow generalizations about the influence of nature and nurture on certain characteristics, but those generalizations do not necessarily apply to the origin of a particular person’s characteristics.

Another misconception about genetic influences is that they are “hard-wired” and thus have inevitable effects. This is true in the case of single-gene disorders such as PKU, but more complex traits—intelligence, for example—are influenced by many genes, as well as by many environmental factors. So genetic influence means just that—influence (Plomin, Owen, & McGuffin, 1994). Genes can affect a trait without completely determining whether or not it will appear.

The Role of Genetic Factors in Psychology

It is no coincidence that the areas of psychology in which genes have been found to play an important role are areas that focus on individual differences—cognitive abilities, personality, and psychological disorders. Much less is known about individual differences in areas such as sensation, perception, consciousness, learning, memory, and motivation and emotion. Consequently, much less behavioral genetics research has been conducted on those variables. Nonetheless, enough is known about genetic

factors to suggest that they probably influence every area of psychology to some extent. In the following sections, we consider behavioral genetics research results that tell a little more of the story about how genes can have an impact on behavior and mental processes.

Genetic Influences over the Life Span

One particularly interesting finding about genetic influences on general cognitive ability is that these influences continue to increase throughout the life span (McGue et al., 1993; Plomin, 1986). That is, the proportion of individual differences (variance) in IQ scores that can be explained by genetic factors increases from 40 percent in childhood to 60 percent in adolescence and young adulthood and then to 80 percent later in life. This increase in the magnitude of genetic influence can be seen, for example, in the expanding difference between IQ correlations for identical twins and those for fraternal twins: Identical twins become more similar in IQ over the life span, whereas fraternal twins become less similar as the years go by. This finding is all the more interesting for overturning the common assumption that environmental influences become increasingly important as accidents, illnesses, and other experiences accumulate throughout life. We still do not have enough data available to permit firm conclusions about whether the magnitude of genetic influences on other traits changes during development.

How can it be that genetic influences become more important over time? One possible explanation is that, as discussed later, genetic predispositions lead people to select, and even create, environments that foster the continued development of their genetically influenced abilities.

Genes Affecting Multiple Traits

Behavioral genetics research has also revealed that genes affecting one trait can sometimes affect others as well. For example, it appears that the same genetic factors affecting anxiety also affect depression (Kendler et al., 1992). So if we could identify specific genes responsible for genetic influences on anxiety, we would expect to find that the same genes were associated with the appearance of depression.

A similar finding has emerged for cognitive ability and scholastic achievement. Tests of scholastic achievement show almost as much genetic influence as do tests of cognitive ability. Moreover, tests of scholastic achievement correlate substantially with tests of cognitive ability. To what extent is a common set of genes responsible for this overlap? Research suggests that the answer is “almost entirely.” It appears that the genes influencing performance on mental ability tests are the same ones that influence students’ performance at school (Wadsworth, 1994).

Identifying Genes Related to Behavior

One of the most exciting new developments in behavioral genetics involves identifying the specific genes responsible for genetic influences in psychology (Plomin & Crabbe, 2000). As noted earlier, for example, there are hundreds of rare, single-gene disorders that affect behavior. One of these is *Huntington’s disease*, an ultimately fatal disorder that involves loss of motor control and progressive deterioration of the central nervous system. Huntington’s disease emerges only in adulthood, beginning with personality changes, forgetfulness, and other behavioral problems. It is caused by a single dominant gene whose identification in 1983 made it possible to determine who will get this disease—even though the mechanism for the disorder is still not understood, and prevention is not yet possible.

Researchers are also tracking down the several genes involved in the appearance of Alzheimer’s disease. (As described in the chapter on biological aspects of

psychology, Alzheimer's disease causes memory loss and increasing confusion in many older people.) One of these genes, a gene that contributes to the risk for late-onset Alzheimer's disease, was identified in 1993. This gene increases the risk for Alzheimer's disease about fivefold, but its presence is neither necessary nor sufficient for the disease to appear. That is, many people with Alzheimer's disease do not have the gene, and many people with the gene do not have the disease. Nonetheless, this gene is by far the strongest risk factor known for Alzheimer's disease, and its discovery marks the beginning of a new era in which specific genes—or regions of DNA near specific genes—will be identified as influencing disorders and psychological traits. Additional examples include reports of linkages between DNA and reading disability (Cardon et al., 1994), hyperactivity (Faraone et al., 2001), and autism (International Molecular Genetic Study of Autism Consortium, 1998). Progress in identifying specific genes in humans has been slower than expected in part because research ethics and common sense prevent the use of selective breeding. Accordingly, human studies have lacked the statistical power needed to detect relatively weak, but still potentially important, genetic influences on behavior (Plomin et al., 2002). However, the more powerful genetic research techniques available in studies of animals have identified several genes associated, for example, with fearfulness (Flint et al., 1995), with sensitivity to drugs such as alcohol (Crabbe et al., 1999), and with various aspects of learning and memory (Wahlsten, 1999).

Future efforts to identify genes related to human behavior will be aided by advances flowing from the Human Genome Project, which in early 2001 succeeded in identifying the sequence of most of the 3 billion “letters” of DNA in the human genome. One of the most surprising findings of that project so far is that the human genome appears to contain only about 30,000 to 40,000 genes—less than half the number expected, and a number that is similar to the estimates for animals such as mice and worms. Does this smaller-than-expected number of human genes mean that there are too few to influence all aspects of human behavior, and that the environment (nurture) must be even more important than we thought in this regard? Not necessarily. It may be that the greater complexity seen in human behavior versus, say, mouse behavior stems not from the number of genes we have but from the greater complexities involved in decoding our genes into proteins. Human genes, more than the genes of other species, are spliced in alternative ways to create a greater variety of proteins. It may be this more subtle *variation* in genes—not the number of genes—that is responsible for differences between mice and people. This possibility has important implications for behavioral genetics because if subtle DNA differences are responsible for the obvious differences between humans and other species, then individual differences within our species—in other words, among people—are likely to involve genetic factors that are even more subtle and hard to find.

Fortunately, new techniques are available that make it possible to detect DNA differences for many thousands of genes simultaneously. These techniques will help in identifying genes related to behavior, a process which will fill in the causal picture about a variety of characteristics and disorders that are influenced by many genes and many environmental factors.

Behavioral Genetics and Environmental Influences

As suggested earlier, research on genetic influences in psychology has also provided some of the best evidence for the importance of environmental influences. It has shown that even though genetic influences are important, they cannot explain everything about human behavior. We must always remember the crucial role of environmental influences—particularly now, when explanations for human behavior seem to increasingly favor nature over nurture.

For example, as already noted, twin and adoption studies have provided evidence of the importance of genetic factors in schizophrenia, and as a result, many

researchers are now trying to identify the specific genes responsible. Enthusiasm for genetic explanations of schizophrenia makes it easy to forget, however, that environmental factors can be at least as important as genes. As described in the chapter on psychological disorders, when one member of an identical-twin pair is schizophrenic, the chances are about 40 percent that the other member of the pair is also schizophrenic. This result surely provides evidence of a strong genetic contribution to schizophrenia, but it also suggests that schizophrenia appears in both identical twins only 40 percent of the time. Most of the time, the identical twin of a person with schizophrenia will not display the disorder. Such differences within pairs of identical twins can be due only to the operation of environmental factors.

In fact, research generally suggests that genetic factors account for less than half of the variance among individuals for psychological characteristics such as personality and psychopathology. This means that at least half of the variance among individuals on these characteristics is due to environmental factors. These environmental—or more properly, *nongenetic*—factors encompass everything other than genetic inheritance. They include such biological factors as prenatal events, nutrition, and illnesses, as well as more traditional environmental factors such as parenting, schooling, and peer influences.

In short, one of the most important findings to emerge from behavioral genetics research has concerned not genetics but the environment. That research suggests that the most important environmental influences are likely to be those that different family members do not share (Plomin, Asbury, & Dunn, 2001). Psychologists need to find out more about these *nonshared factors* and how they act to create differences in children—twins or not—who grow up in the same family (Turkheimer & Waldron, 2000).

So far, research on this topic has shown that children growing up in the same family actually experience quite different environments, especially in relation to their parents. Siblings perceive that their parents treat them very differently—and indeed, observational studies back up such perceptions of differential treatment (Plomin, Asbury, & Dunn, 2001). Even events such as parental divorce, which would seem to be shared by all children in the family, appear to be experienced very differently by each child, depending especially upon age, personality, and the nature of the relationship with each parent.

Research is also beginning to focus on environmental influences beyond the family—such as relationships with teachers or friends—which are even more likely than home-related factors to vary among siblings. If you have a brother or sister, think about a psychological trait on which you and your sibling differ—confidence, for example. Why do you think you two are different on that trait? Perhaps one of you experienced a loss of self-confidence when faced with the demands of an impatient grade school teacher or after being betrayed by a childhood friend. Did these differing experiences occur randomly and thus make you considerably more confident or less confident than your sibling? Or is it possible that differences in your genetic makeups helped bring about these different experiences? Unless you and your sibling are identical twins, you share only about 50 percent of your genes. Perhaps genetically influenced differences between the two of you—in emotionality or other aspects of temperament, for example—caused parents, peers, and others to respond to each of you differently. This brings us to the second major discovery about the environment to emerge from research on behavioral genetics: Environmental influences that appear to cause differences between siblings might themselves be caused by genetic differences between the siblings.

In the past decade, most of the measures used by psychologists to assess environmental factors have been shown to be influenced by genetic factors (Plomin & Bergeman, 1991). These measures include, for example, adolescents' ratings of how their parents treated them, observations of parent-child interactions, and questionnaires about life events and social support. If scores on measures such as these reflected only environmental factors, then the scores of identical twins should

TRY THIS

be no more similar to each other than those of fraternal twins. By the same token, there should be little similarity in environmental-experience measures for genetically related individuals who grew up in different families.

The results reported by behavioral geneticists do not fit these expectations (Plomin, 1994b; Reiss et al., 2000). For example, parents differ in terms of how responsive they are to their children, but these differences in responsiveness correlate with the children's cognitive ability—a trait that has a clear genetic component. So, as described in the chapters on cognitive abilities and human development, parental responsiveness can influence cognitive development, and—as behavioral genetics research suggests—children's inherited cognitive abilities can alter the responsiveness of their parents. That is, parents tend to be more responsive to bright children who ask lots of questions and are interested in the answers.

Outside the family, too, genetic factors appear to play a role in generating environmental experiences (Harris, 1998). For example, research on the characteristics of children's peer groups shows that children tend to choose their friends—and to be chosen as friends—partly on the basis of genetically influenced traits, such as mental ability and temperament (Manke et al., 1995). Several studies also suggest that genetic factors can increase or decrease the likelihood of family conflicts and other social stressors that threaten one's physical and psychological well-being (Reiss et al., 2000).

An important implication of genetic influences on environmental events is that measuring the impact of family relationships, peer influences, and other environmental factors on behavior and mental processes may be more difficult than psychologists thought. A measure that is aimed at assessing an environmental factor may nonetheless be affected by the genetic characteristics of the people being studied.

In human development, nature and nurture work together. Children select, modify, and create environments that are correlated with their genetic inclinations. As developmental psychologists have long argued, children are not formless blobs of clay passively molded by the environment. Rather, they are active participants in their experiences. The new findings we have described here suggest that genetics plays an important role in those experiences (Plomin, 1994b).

SUMMARY

Behavioral genetics is the study of how genes affect behavior.

The Biology of Genetics and Heredity

Research on the ways in which nature and nurture interact to shape behavior and mental processes requires a knowledge of *genetics*, the biology of inheritance. The genetic code that transmits characteristics from one generation to the next is contained in the *deoxyribonucleic acid* (DNA) that makes up the *genes* that in turn make up *chromosomes*. Dominant genes are expressed whenever they are present; recessive genes are expressed only when inherited from both parents. Most human characteristics are controlled by more than one gene; they are *polygenic*. The genes in a person's forty-six chromosomes make up the *genotype*; the *phenotype*—how people actually look and act—is influenced by genes and the environment.

A Brief History of Genetic Research in Psychology

Sir Francis Galton's work in the nineteenth century helped to stimulate psychologists' interest in the influence of genetics on behavior. The popularity of research in this area has waxed and waned over the years, but today most psychologists recognize the role of genetic, as well as environmental, influences on many aspects of behavior and mental processes.

The Focus of Research in Behavioral Genetics

Behavioral genetics research identifies the genetic and environmental factors responsible for differences among individuals, not for the characteristics of a particular person. Although genes

can influence a trait, they may not completely determine whether that trait appears.

The Role of Genetic Factors in Psychology

Genetic factors probably influence, to some extent, every aspect of behavior and mental processes.

Genetic Influences over the Life Span

Genetic influences on general cognitive ability appear to increase over time, possibly because genetic predispositions lead people to select, and even create, environments that foster the continued development of abilities that are in line with those predispositions.

Genes Affecting Multiple Traits

Genes that affect one trait, such as anxiety, can sometimes also affect other traits, such as depression.

Identifying Genes Related to Behavior

Current research in behavioral genetics, aided by findings from the Human Genome Project, is identifying specific genes responsible for specific characteristics—especially rare, single-gene disorders such as Huntington's disease.

Behavioral Genetics and Environmental Influences

Research in behavioral genetics has actually provided evidence for the importance of environmental influences, too, because the research shows that genetics alone cannot account for such characteristics as intelligence, personality, and psychological disorders. Some of the most important environmental influences are likely to be those that members of the same family do not share. In short, neither nature nor nurture is conducting the performance of the other: They are playing a duet.

Statistics in Psychological Research

Understanding and interpreting the results of psychological research depends on *statistical analyses*, which are methods for describing and drawing conclusions from data. The chapter on research in psychology introduced some terms and concepts associated with *descriptive statistics*—the numbers that psychologists use to describe and present their data—and with *inferential statistics*—the mathematical procedures used to draw conclusions from data and to make inferences about what they mean. Here, we present more details about these statistical analyses that will help you to evaluate research results.

Describing Data

To illustrate our discussion, consider a hypothetical experiment on the effects of incentives on performance. The experimenter presents a list of mathematics problems to two groups of participants. Each group must solve the problems within a fixed time, but for each correct answer, the low-incentive group is paid ten cents whereas the high-incentive group gets one dollar. The hypothesis to be tested is the **null hypothesis**, the assertion that the independent variable manipulated by the experimenter will have no effect on the dependent variable measured by the experimenter. In this case, the null hypothesis holds that the size of the incentive (the independent variable) will not affect performance on the mathematics task (the dependent variable).

Assume that the experimenter has obtained a random sample of participants, assigned them randomly to the two groups, and done everything possible to avoid the confounds and other research problems discussed in the chapter on research in psychology. The experiment has been run, and the psychologist now has the data: a list of the number of correct answers given by each participant in each group. Now comes the first task of statistical analysis: describing the data in a way that makes them easy to understand.

The Frequency Histogram

The simplest way to describe the data is to draw up something like Table 1, in which all the numbers are simply listed. After examining the table, you might discern that the high-incentive group seems to have done better than the low-incentive group, but the difference is not immediately obvious. It might be even harder to see if more participants had been involved and if the scores included three-digit numbers. A picture is worth a thousand words, so a more satisfactory way of presenting the same data is in a picture-like graphic known as a **frequency histogram** (see Figure 1).

Construction of a histogram is simple. First, divide the scale for measuring the dependent variable (in this case, the number of correct solutions) into a number of categories, or “bins.” The bins in our example are 1–2, 3–4, 5–6, 7–8, and 9–10. Next, sort the raw data into the appropriate bin. (For example, the score of a participant who had 5 correct answers would go into the 5–6 bin, a score of 8 would go into the 7–8 bin, and so on.) Finally, for each bin, count the number of scores in that bin and draw a bar up to the height of that number on the vertical axis of a graph. The set of bars makes up the frequency histogram.

Because we are interested in comparing the scores of two groups, there are separate histograms in Figure 1: one for the high-incentive group and one for the low-incentive group. Now the difference between groups that was difficult to see in Table 1 becomes clearly visible: More people in the high-incentive group obtained high scores than in the low-incentive group.

null hypothesis The assertion that the independent variable manipulated by the experimenter will have no effect on the dependent variable measured by the experimenter.

frequency histogram A graphic presentation of data that consists of a set of bars, each of which represents how frequently different values of variables occur in a data set.

descriptive statistics Numbers that summarize a set of research data.

range A measure of variability that is the difference between the highest and the lowest value in a data set.

Here are the test scores obtained by thirteen participants performing under low-incentive conditions and thirteen participants performing under high-incentive conditions.

figure 1

Frequency Histograms

The height of each bar of a histogram represents the number of scores falling within each range of score values. The pattern formed by these bars gives a visual image of how research results are distributed.

Low incentive

(A)

High incentive

(B)

Histograms and other pictures of data are useful for visualizing and better understanding the “shape” of research data, but in order to analyze data statistically, we need to use other ways of handling the data that make up these graphic presentations. For example, before we can tell whether two histograms are different statistically or just visually, the data they represent must be summarized using descriptive statistics.

Descriptive Statistics

The four basic categories of descriptive statistics (1) measure the number of observations made; (2) summarize the typical value of a set of data; (3) summarize the spread, or variability, in a set of data; and (4) express the correlation between two sets of data.

N The easiest statistic to compute, abbreviated as *N*, simply describes the number of observations that make up the data set. In Table 1, for example, *N* = 13 for each group, or 26 for the entire data set. Simple as it is, *N* plays a very important role in more sophisticated statistical analyses.

Measures of Central Tendency It is apparent in the histograms in Figure 1 that there is a difference in the pattern of scores between the two groups. But how much of a difference? What is the typical value, the *central tendency*, that represents each group’s performance? As described in the chapter on research in psychology, there are three measures that capture this typical value: the mode, the median, and the mean. Recall that the *mode* is the value or score that occurs most frequently in the data set. The *median* is the halfway point in a set of data: Half the scores fall above the median, half fall below it. The *mean* is the arithmetic average. To find the mean, add the values of all the scores and divide by the number of scores.

Measures of Variability The variability, or spread, or dispersion of a set of data is often just as important as its central tendency. This variability can be quantified by measures known as the *range* and the *standard deviation*.

As described in the chapter on research in psychology, the *range* is simply the difference between the highest and the lowest value in a data set. For the data in Table 1, the range for the low-incentive group is $9 - 2 = 7$; for the high-incentive group, the range is $10 - 3 = 7$.

The **standard deviation**, or **SD**, measures the average difference between each score and the mean of the data set. To see how the standard deviation is calculated, consider the data in Table 2. The first step is to compute the mean of the set—in this case, $20/5 = 4$. Second, calculate the difference, or *deviation* (*D*), of each score from the mean by subtracting the mean from each score, as in column 2 of Table 2. Third, find the average of these deviations. However, if you calculated the average by finding the arithmetic mean, you would sum the deviations and find that the negative deviations exactly balance the positive ones, resulting in a mean difference of 0. Obviously there is more than zero variation around the mean in the data set. So, instead of employing the arithmetic mean, we compute the standard deviation by first squaring the deviations (which removes any negative values), summing these squared deviations, dividing by *N*, and then taking the square root of the result. These simple steps are outlined in more detail in Table 2.

The Normal Distribution Now that we have described histograms and reviewed some descriptive statistics, we will re-examine how these methods of representing research data relate to some of the concepts discussed elsewhere in the book.

In most subfields in psychology, when researchers collect many measurements and plot their data in histograms, the pattern that results often resembles that shown for the low-incentive group in Figure 1. That is, the majority of scores tend to fall in the middle of the distribution, with fewer and fewer occurring as one moves toward the extremes. As more and more data are collected, and as smaller and smaller bins are used (perhaps containing only one value each), the histograms tend to smooth out until they resemble the bell-shaped curve known as the **normal distribution**, or *normal curve*, which is shown in Figure 2(A). When a distribution of scores follows a truly normal curve, its mean, median, and mode all have the same value. Furthermore, if the curve is normal, we can use its standard deviation to describe how any particular score stands in relation to the rest of the distribution.

IQ scores provide an example. They are distributed in a normal curve, with a mean, median, and mode of 100 and an SD of 16—as shown in Figure 2(B). In such a distribution, half of the population will have an IQ above 100, and half will be below 100. The shape of the true normal curve is such that 68 percent of the area under it lies within one standard deviation above and below the mean. In terms of IQ, this means that 68 percent of the population has an IQ somewhere between 84 (100 minus 16) and 116 (100 plus 16). Of the remaining 32 percent of the

The standard deviation of a set of scores reflects the average degree to which those scores differ from the mean of the set.

table 2
Calculating the Standard Deviation

Raw Data	Difference from Mean = <i>D</i>	<i>D</i> ²
2	2 − 4 = − 2	4
2	2 − 4 = − 2	4
3	3 − 4 = − 1	1
4	4 − 4 = 0	0
9	9 − 4 = 5	25
Mean = 20/5 = 4		Σ <i>D</i> ² = 34

Standard deviation = $\sqrt{\frac{\sum D^2}{N}} = \sqrt{\frac{34}{5}} = \sqrt{6.8} = 2.6$

Note: Σ means “the sum of.”

figure 2

The Normal Distribution

Many kinds of research data approximate the symmetrical shape of the normal curve, in which most scores fall toward the center of the range.

Normal distribution, showing the smoothed approximation to the frequency histogram

(A)

The normal distribution of IQ

(B)

standard deviation (SD) A measure of variability that is the average difference between each score and the mean of the data.

normal distribution A dispersion of scores such that the mean, median, and mode all have the same value. When a distribution has this property, the standard deviation can be used to describe how any particular score stands in relation to the rest of the distribution.

percentile score The percentage of people or observations that fall below a given score in a normal distribution.

standard score A value that indicates the distance, in standard deviations, between a given score and the mean of all the scores in a data set.

population, half falls more than 1 SD above the mean, and half falls more than 1 SD below the mean. Thus, 16 percent of the population has an IQ above 116, and 16 percent scores below 84.

The normal curve is also the basis for percentiles. A **percentile score** indicates the percentage of people or observations that fall below a given score in a normal distribution. In Figure 2(B), for example, the mean score (which is also the median) lies at a point below which 50 percent of the scores fall. Thus, the mean of a normal distribution is at the 50th percentile. What does this say about IQ? If you score 1 SD above the mean, your score is at a point above which only 16 percent of the population falls. This means that 84 percent of the population (100 percent minus 16 percent) must be below that score; so this IQ score is at the 84th percentile. A score at 2 SDs above the mean is at the 97.5 percentile, because only 2.5 percent of the scores are above it in a normal distribution.

Scores may also be expressed in terms of their distance in standard deviations from the mean, producing what are called **standard scores**. A standard score of 1.5, for example, is 1.5 standard deviations from the mean.

Correlation Histograms and measures of central tendency and variability describe certain characteristics of one dependent variable at a time. However,

psychologists are often concerned with describing the *relationship* between two variables. Measures of correlation are frequently used for this purpose. We discussed the interpretation of the *correlation coefficient* in the chapter on research in psychology; here we describe how to calculate it.

Recall that correlations are based on the relationship between two numbers associated with each participant or observation. The numbers may represent, say, a person's height and weight or the IQs of a parent and child. Table 3 contains this kind of data for four participants from our incentives study who took the test twice. (As you may recall from the chapter on cognitive abilities, the correlation between their scores would be a measure of *test-retest reliability*.) The formula for computing the Pearson product-moment correlation, or r , is as follows:

$$r = \frac{\sum (x - M_x)(y - M_y)}{\sqrt{\sum (x - M_x)^2 \sum (y - M_y)^2}}$$

where:

- x = each score on variable 1 (in this case, test 1)
- y = each score on variable 2 (in this case, test 2)
- M_x = the mean of the scores on variable 1
- M_y = the mean of the scores on variable 2

The main function of the denominator in this formula is to ensure that the coefficient ranges from +1.00 to -1.00, no matter how large or small the values of the variables being correlated. The “action element” of this formula is the numerator. It is the result of multiplying the amounts by which each of two observations (x and y) differ from the means of their respective distributions (M_x and M_y). Notice that, if the two variables “go together” (so that, if one is large, the other is also large, and if one is small, the other is also small), then either both will tend to be above the mean of their distribution or both will tend to be below the mean of their distribution. When this is the case, $x - M_x$ and $y - M_y$ will both be positive, or they will both be negative. In either case, their product will always be positive, and the correlation coefficient will also be positive. If, on the other hand, the two variables go opposite to one another, such that, when one is large, the other is small, one of them is likely to be smaller than the mean of its distribution, so that either $x - M_x$ or $y - M_y$ will have a negative sign, and the other will have a positive sign. Multiplying these differences together will always result in a product with a negative sign, and r will be negative as well.

table 3

Calculating the Correlation Coefficient

Participant	Test 1	Test 2	$(x - M_x)(y - M_y)^{(b)}$
A	1	3	$(1 - 3)(3 - 4) = (-2)(-1) = +2$
B	1	3	$(1 - 3)(3 - 4) = (-2)(-1) = +2$
C	4	5	$(4 - 3)(5 - 4) = (1)(1) = +1$
D	6	5	$(6 - 3)(5 - 4) = (3)(1) = +3$
	$^{(a)}M_x = 3$	$M_y = 4$	$\sum (x - M_x)(y - M_y) = +8$

$$^{(c)}\sum (x - M_x)^2 = 4 + 4 + 1 + 9 = 18$$

$$^{(d)}\sum (y - M_y)^2 = 1 + 1 + 1 + 1 = 4$$

$$^{(e)}r = \frac{\sum (x - M_x)(y - M_y)}{\sqrt{\sum (x - M_x)^2 \sum (y - M_y)^2}} = \frac{8}{\sqrt{18 \times 4}} = \frac{8}{\sqrt{72}} = \frac{8}{8.48} = +.94$$

Though it appears complex, calculation of the correlation coefficient is quite simple. The resulting r reflects the degree to which two sets of scores tend to be related, or to co-vary.

Now compute the correlation coefficient for the data presented in Table 3. The first step (step a in the table) is to compute the mean (M) for each variable. M_x turns out to be 3 and M_y is 4. Next, calculate the numerator by finding the differences between each x and y value and its respective mean and by multiplying them (as in step b of Table 3). Notice that, in this example, the differences in each pair have like signs, so the correlation coefficient will be positive. The next step is to calculate the terms in the denominator; in this case, as shown in steps c and d in Table 3, they have values of 18 and 4. Finally, place all the terms in the formula and carry out the arithmetic (step e). The result in this case is an r of $+.94$, a high and positive correlation suggesting that performances on repeated tests are very closely related. A participant doing well the first time is very likely to do well again; a person doing poorly at first will probably do no better the second time.

Inferential Statistics

The descriptive statistics from the incentives experiment tell the experimenter that the performances of the high- and low-incentive groups differ. But there is some uncertainty. Is the difference large enough to be important? Does it represent a stable effect or a fluke? The researcher would like to have some *measure of confidence* that the difference between groups is genuine and reflects the effect of incentive on mental tasks in the real world, rather than the effect of random or uncontrolled factors. One way of determining confidence would be to run the experiment again with a new group of participants. Confidence that incentives produced differences in performance would grow stronger if the same or a larger between-group difference occurs again. In reality, psychologists rarely have the opportunity to repeat, or *replicate*, their experiments in exactly the same way three or four times. But **inferential statistics** provide a measure of how likely it was that results came about by chance. They put a precise mathematical value on the confidence or probability that rerunning the same experiment would yield similar (or even stronger) results.

Differences Between Means: The t Test

One of the most important tools of inferential statistics is the t test. It allows the researcher to ask how likely it is that the difference between two means occurred by chance rather than as a function of the effect of the independent variable. When the t test or other inferential statistic says that the probability of chance effects is small enough (usually less than 5 percent), the results are said to be *statistically significant*. Conducting a t test of statistical significance requires the use of three descriptive statistics.

The first component of the t test is the size of the observed effect, the difference between the means. Recall that the mean is calculated by summing a group's scores and dividing by the number of scores. In the example shown in Table 1, the mean of the high-incentive group is $94/13$, or 7.23 , and the mean of the low-incentive group is $65/13$, or 5 . Thus, the difference between the means for the high- and low-incentive groups is $7.23 - 5 = 2.23$.

Second, the standard deviation of scores in each group must be known. If the scores in a group are quite variable, the standard deviation will be large, indicating that chance may have played a large role in producing the results. The next replication of the study might generate a very different set of group scores. If the scores in a group are all very similar, however, the standard deviation will be small, which suggests that the same result would probably occur for that group if the study were repeated. Thus, the *difference* between groups is more likely to be significant when each group's standard deviation is small. If variability is high enough that the scores of two groups overlap (in Table 1, for example, some people in the low-incentive group actually did better on the math test than some in the high-incentive group), the mean difference, though large, may not be statistically significant.

inferential statistics A set of procedures that provides a measure of how likely it is that research results came about by chance.

Third, we need to take the sample size, N , into account. The larger the number of participants or observations, the more likely it is that a given difference between means is significant. This is so because, with larger samples, random factors within a group—the unusual performance of a few people who were sleepy or anxious or hostile, for example—are more likely to be canceled out by the majority, who better represent people in general. The same effect of sample size can be seen in coin tossing. If you toss a quarter five times, you might not be too surprised if heads comes up 80 percent of the time. If you get 80 percent heads after one hundred tosses, however, you might begin to suspect that this is probably not due to chance alone and that some other effect, perhaps some bias in the coin, is significant in producing the results. (For the same reason, a relatively small correlation coefficient—between diet and grades, say—might be statistically significant if it was based on 50,000 students. As the number of participants increases, it becomes less likely that the correlation reflects the influence of a few oddball cases.)

To summarize, as the differences between the means get larger, as N increases, and as standard deviations get smaller, t increases. This increase in t raises the researcher's confidence in the significance of the difference between means.

Now we will calculate the t statistic and show how it is interpreted. The formula for t is:

$$t = \frac{(M_1 - M_2)}{\sqrt{\frac{(N_1 - 1)S_1^2 + (N_2 - 1)S_2^2}{N_1 + N_2 - 2} \left(\frac{N_1 + N_2}{N_1 N_2} \right)}}$$

where:

M_1 = mean of group 1

M_2 = mean of group 2

N_1 = number of scores or observations for group 1

N_2 = number of scores or observations for group 2

S_1 = standard deviation of group 1 scores

S_2 = standard deviation of group 2 scores

Despite appearances, this formula is quite simple. In the numerator is the difference between the two group means; t will get larger as this difference gets larger. The denominator contains an estimate of the standard deviation of the *differences* between group means; in other words, it suggests how much the difference between group means would vary if the experiment were repeated many times. Since this estimate is in the denominator, the value of t will get smaller as the standard deviation of group differences gets larger. For the data in Table 1,

$$\begin{aligned} t &= \frac{(M_1 - M_2)}{\sqrt{\frac{(N_1 - 1)S_1^2 + (N_2 - 1)S_2^2}{N_1 + N_2 - 2} \left(\frac{N_1 + N_2}{N_1 N_2} \right)}} \\ &= \frac{7.23 - 5}{\sqrt{\frac{(12)(5.09) + (12)(4.46)}{24} \left(\frac{26}{169} \right)}} \\ &= \frac{2.23}{\sqrt{.735}} = 2.60 \text{ with 24 df} \end{aligned}$$

To determine what a particular t means, we must use the value of N and a special statistical table called, appropriately enough, the t table. We have reproduced part of the t table in Table 4.

This table allows the researcher to determine whether an obtained t value is statistically significant. If the t value is larger than the one in the appropriate row in the .05 column, the difference between means that generated that t score is usually considered statistically significant.

table 4
The t Table

df	p Value		
	.10 (10%)	.05 (5%)	.01 (1%)
4	1.53	2.13	3.75
9	1.38	1.83	2.82
14	1.34	1.76	2.62
19	1.33	1.73	2.54
22	1.32	1.71	2.50
24	1.32	1.71	2.49

First, find the computed values of t in the row corresponding to the **degrees of freedom**, or df , associated with the experiment. In this case, degrees of freedom are simply $N_1 + N_2 - 2$ (or two less than the total sample size or number of scores). Since our experiment had 13 participants per group, $df = 13 + 13 - 2 = 24$. In the row for 24 df in Table 4, you will find increasing values of t in each column. These columns correspond to decreasing p values, the probabilities that the difference between means occurred by chance. If an obtained t value is equal to or larger than one of the values in the t table (on the correct df line), then the difference between means that generated that t is said to be significant at the .10, .05, or .01 level of probability. Suppose, for example, that an obtained t (with 19 df) was 2.00. Looking along the 19 df row, you find that 2.00 is larger than the value in the .05 column. This allows you to say that the probability that the difference between means occurred by chance was no greater than .05, or 5 in 100. If the t had been less than the value in the .05 column, the probability of a chance result would have been greater than .05. As noted earlier, when an obtained t is not large enough to exceed t table values at the .05 level, at least, it is not usually considered statistically significant.

The t value from our experiment was 2.60, with 24 df . Because 2.60 is greater than all the values in the 24 df row, the difference between the high- and low-incentive groups would have occurred by chance less than 1 time in 100. In other words, the difference is statistically significant.

Beyond the t Test

Many experiments in psychology are considerably more complex than simple comparisons between two groups. They often involve three or more experimental and control groups. Some experiments also include more than one independent variable. For example, suppose we had been interested not only in the effect of incentive size on performance but also in the effect of problem difficulty. We might then create six groups whose members would perform easy, moderate, or difficult problems with low or high incentives.

In an experiment like this, the results might be due to the incentive, the problem difficulty, or the combined effects (known as the *interaction*) of the two. Analyzing the size and source of these effects is typically accomplished through procedures known as *analysis of variance*. The details of analysis of variance are beyond the scope of this book; for now, note that the statistical significance of each effect is influenced by differences between means, standard deviation, and sample size in much the same way as described for the t test.

For more detailed information about how analysis of variance and other inferential statistics are used to understand and interpret the results of psychological

degrees of freedom (df) The total sample size or number of scores in a data set, less the number of experimental groups.

research, consider taking courses in research methods and statistical or quantitative methods.

SUMMARY

Psychological research generates large quantities of data. Statistics are methods for describing and drawing conclusions from data.

Describing Data

Researchers often test the *null hypothesis*, which is the assertion that the independent variable will have no effect on the dependent variable.

The Frequency Histogram

Graphic representations such as *frequency histograms* provide visual descriptions of data, making the data easier to understand.

Descriptive Statistics

Numbers that summarize a set of data are called *descriptive statistics*. The easiest statistic to compute is N , which gives the number of observations made. A set of scores can be described by two other types of descriptive statistics: a measure of central tendency, which describes the typical value of a set of data, and a measure of variability. Measures of central tendency include the mean, median, and mode; variability is typically measured by the *range* and by the standard deviation. Sets of data often follow a *normal distribution*, which means that most scores fall in the middle of the range, with fewer and fewer scores occurring as one moves toward the extremes. In a truly normal distribution the mean, median, and mode are identical. When a set of data shows a normal distribution, a data point can be cited

in terms of a *percentile score*, which indicates the percentage of people or observations falling below a certain score, and in terms of *standard scores*, which indicate the distance, in standard deviations, that a score is located from the mean. Another type of descriptive statistic, a correlation coefficient, is used to measure the correlation between sets of scores.

Inferential Statistics

Researchers use *inferential statistics* to quantify the probability that conducting the same experiment again would yield similar results.

Differences Between Means: The t Test

One inferential statistic, the t test, assesses the likelihood that differences between two means occurred by chance or reflect the effect of an independent variable. Performing a t test requires using the difference between the means of two sets of data, the *standard deviation* of scores in each set, and the number of observations or participants. Interpreting a t test requires that *degrees of freedom* also be taken into account. When the t test indicates that the experimental results had a low probability of occurring by chance, the results are said to be statistically significant.

Beyond the t Test

When more than two groups must be compared, researchers typically rely on analysis of variance in order to interpret the results of an experiment.

SUBJECT INDEX/GLOSSARY

Key terms, which appear in boldface, are followed by their definitions.

- Abecedarian Project**, 361–362
- Abnormality**, 554–555. *See also* Psychological disorders
- Absolute threshold** *The minimum amount of stimulus energy that can be detected 50 percent of the time*, 146, 147–149
- Abuse**, false memories and, 250, 251, 252, 253
- Academic achievement**
genetics and, A-5
language and, 450–451
socioeconomic status and, 451–452
- Accessory structures** *Structures, such as the lens of the eye, that modify a stimulus*, 101
- Accidental reinforcement**, 204
- Accommodation** *(in cognitive development) The process of modifying schemas as an infant tries out familiar schemas on objects that do not fit them*, 441
- Accommodation** *(in eye structure) The ability of the lens to change its shape and bend light rays so that objects are in focus*, 112–113, 160, 173
- Acetylcholine** *A neurotransmitter used by neurons in the peripheral and central nervous systems in the control of functions ranging from muscle contraction and heart rate to digestion and memory*, 87, 90, 91, 255, 336, 416
- Achievement motivation**, 404–409
development of, 405–406
goal setting and, 406–407
individual differences in, 404–405
need for achievement and, 404–406
subjective well-being and, 408–409
success in workplace and, 407–408
- Achievement tests** *Measures of what a person has accomplished or learned in a particular area*, 350
- Acoustic encoding** *The mental representation of information as a sequence of sounds*, 226, 233–234
- Acquired immune deficiency syndrome (AIDS)**, 95, 396, 399, 469, 486, 501, 504, 505, 509, 511
- Acrophobia**, 566, 567
- ACT**, *see* American College Testing Assessment
- Action potential** *An abrupt wave of electrochemical changes traveling down an axon when a neuron becomes depolarized*, 58–60, 61, 102
- Activation-synthesis theory**, 326
- Active learning**, 219–220
- Actor-observer bias** *The tendency to attribute other people's behavior to internal causes while attributing one's own behavior (especially errors and failures) to external causes*, 658–659
- Actualizing tendency** *According to Rogers, an innate inclination toward growth that motivates all people to seek the full realization of their highest potential*, 538, 539
- Acuity** *Visual clarity, which is greatest in the fovea because of its large concentration of cones*, 114
- Acupuncture**, 69, 135–136
- Adam**, *see* MDMA
- Adaptation** *The process through which responsiveness to an unchanging stimulus decreases over time*,
dark, 113–114
diseases of, 492
general adaptation syndrome and, 491–492, 501
learning and, 185
sensory systems and, 101, 131
- Addiction** *Development of a physical need for a psychoactive drug*, 332, 595. *See also* Psychoactive drugs
- Additive color mixing**, 121
- A-delta fibers**, 133
- Adenosine**, 325, 336
- ADHD**, *see* Attention deficit hyperactivity disorder
- Adolescence**, 467–474
cognitive development in, 440, 446, 471, 480
depression in, 576, 581, 582
early, 467, 480
eating disorders in, 394–395
genital stage in, 522
identity formation in, 460, 469–471
late, 471, 480
moral reasoning in, 472–474
peer relationships in, 461, 468
physical development in, 468, 469, 480
pregnancy in, 469
puberty and, 398, 467–469
sexual behavior in, 399, 469
sleep in, 321
social and emotional development in, 457, 460, 462, 467–471, 480
suicide in, 578
- Adoption studies**, 51–52, A-3
- Adrenal glands**, 93, 94, 95, 505, 507
general adaptation syndrome and, 491, 492
- Adrenaline**, *see* Epinephrine
- Adrenocorticotrophic hormone (ACTH)**, 94, 95
general adaptation syndrome and, 491–492
- Adulthood**, 474–482
cognitive changes in, 84–86, 370–372, 440, 471, 474–477, 480, 481
early, 474, 475, 478–479
middle, 474, 475, 479–480
moral reasoning in, 472, 473
physical changes in, 474, 480
social and emotional changes in, 460, 477–481
see also Late adulthood
- Advertising**
cultural differences and, 23, 304
errors in formal reasoning and, 276
memory and, 229
subliminal, 147–149
- Aerophobia**, 566, 614, 617
- Affective disorder**, *see* Mood disorder
- Afferent neurons**, 67
- Afghanistan**, Taliban and, 693, 697
- Afterimages**, 123, 124
- Age regression**, hypnosis and, 327, 328, 329
- Aggression** *An act that is intended to cause harm or damage to another person*, 694–702
acquaintances and, 694–695
alcohol and, 332, 334
androgens and, 93
arousal and, 698–701
biological approach to, 695–696
cognitive approach to, 19
copycat crimes and, 680
culture and, 208, 695, 696–697
day care and, 37
defensive, 695–696
environment and, 695, 697, 698–699, 701–702
evolutionary approach to, 17, 383, 695
frustration and, 698
humanistic approach to, 19
learning and, 696–697
observational learning and, 214
physical punishment and, 206
pornography and, 37, 699–701
prevalence of, 694
psychodynamic approach to, 18, 520
reasons for, 695–697
serotonin and, 88
as stress response, 495
television and, 37, 215–217, 697
temperature and, 697, 701
- Aging**, *see* Late adulthood
- Agonists** *Drugs that mimic the effects of the neurotransmitter that normally binds to a neural receptor*, 331
- Agoraphobia** *A strong fear of being alone or away from the security of home*, 566–567, 568, 617, 627, 637, 640
- Agranulocytosis**, 635
- Agreeableness**, as big-five personality factor, 528
- AI**, *see* Artificial intelligence
- AIDS**, *see* Acquired immune deficiency syndrome
- Air pollution**, aggression and, 702
- Alarm reaction**, general adaptation syndrome and, 491
- Alcohol**, 332, 333–334, 335
aggression and, 696
alcohol use disorders and, *see* Alcoholism
cerebellum and, 71
fetal alcohol syndrome and, 436, 509, 596
health problems and, 509
social drinking and, 597
- Alcoholics Anonymous (AA)**, 620
- Alcoholism** *A pattern of drinking that may lead to addiction and almost always causes severe social, physical, and other problems*, 558, 596–597, 598, 620, 621, 627, 641, A-6

- Algorithms** *Systematic procedures that cannot fail to produce a solution to a problem*, 274, 277
- Alpha waves**, 318
- Alprazolam (Xanax)**, 637, 638, 640, 641
- Altered state of consciousness** *A condition in which changes in mental processes are extensive enough that a person or others notice significant differences in psychological and behavioral functioning*, 317
- Altruism** *An unselfish concern for another's welfare*, 702–703. *See also* Altruism/helping behavior
- Altruism/helping behavior**, 702–709
- arousal: cost-reward theory of, 703–706, 709
 - children and, 703
 - empathy-altruism theory of, 706, 709
 - evolutionary approach to, 383, 706–709
 - examples of, 702–703
- Alzheimer's disease**, 55, 57, 73–75, 84, 87, 89, 91, 92, 194–195, 255, 323, 371, 474, 476–477, 557, A-5–A-6
- American Association of Suicidology**, 578
- American Cancer Society**, 508
- American College Testing Assessment (ACT)**, 350
- American Law Institute (ALI)**, 599
- American Medical Association**, 341
- American Psychiatric Association**, 400, 555, 560
- American Psychological Association**, 16, 49, 352, 513, 549, 626–628, 631, A-3
- American Psychological Association Commission on Violence and Youth**, 215
- American Sign Language**, 111, 301, 303
- Amitid**, *see* Amitriptyline
- Amitriptyline (Elavil; Amitid)**, 638
- Amnesia**, 229, 562
- anterograde, 256, 257, 316, 317
 - dissociative, 573
 - infantile, 449–450
 - posthypnotic, 327
 - retrograde, 256, 257
- Amphetamines**, 335, 386, 696
- Amplitude** *The difference between the peak and the baseline of a waveform*, 104, 105, 106
- Amygdala** *A structure in the forebrain that, among other things, associates features of stimuli from two sensory modalities, such as linking the shape and feel of objects in memory*, 72–73, 86, 127, 414, 666
- Amyloid vaccines**, 74
- Anabolic effects**, 390
- Anafranil**, *see* Clomipramine
- Analgesia** *The absence of the sensation of pain in the presence of a normally painful stimulus*, 134–135
- Analogical representations**, 273
- Analogies**, 280–282, 285
- Analogous methodology**, 707–709
- Anal stage** *The second of Freud's psychosexual stages, usually occurring during the second year of life, in which the focus of pleasure and conflict shifts from the mouth to the anus*, 521
- Analysis of variance**, A-17–A-18
- Analytic intelligence**, 366, 367, 368
- Analytic psychology**, 522
- Anandamide**, 338
- Anchoring heuristic** *A mental shortcut that involves basing judgments on existing information*, 277–278
- Androgens** *Masculine hormones that circulate in the bloodstream and regulate sexual motivation in both sexes; relatively more androgens circulate in men than in women*, 93, 398, 401
- Anesthesia, consciousness and**, 309, 312
- Anger, facial expression of**, 425
- Animal studies**
- of acupuncture, 136
 - of addiction, 332, 336, 340
 - of aggression, 695
 - of brain plasticity, 85
 - of consciousness, 309
 - of dopamine, 88
 - of dreams, 326
 - of emotion, 421
 - ethics and, 49
 - of gene manipulation in animal models of human disease, 73–75
 - of genetic influences on behavior, A-6
 - of hunger and satiety, 389, 390, 391
 - of insight, 212–213
 - of language use, 301–303
 - of latent learning, 211
 - of learned helplessness, 209
 - of nootropic drugs, 90–91
 - of olfaction, 127
 - of pain, 134, 135
 - of personality, 528
 - selective breeding and, 50
 - of sex hormones, 93
 - of sexual behavior, 396, 398, 401
 - social cognitive neuroscience and, 665–666
 - of stress, 96
 - of synaptic plasticity, 82–84
 - of taste, 129–130, 193
 - of touch, 132
 - of vision, 116
 - of wanting and liking, 387
 - of weight loss, 393–394
- Animal Welfare Act**, 49
- Animism**, 445
- "Anna O."**, 606
- Anorexia nervosa** *An eating disorder characterized by self-starvation and dramatic weight loss*, 394
- Antagonists** *Drugs that bind to a receptor and prevent the normal neurotransmitter from binding*, 331
- Anterior cingulate cortex**, 133
- Anterograde amnesia** *A loss of memory for any event that occurs after a brain injury*, 256, 257, 316, 317
- Anti-anxiety agents**, *see* Anxiolytics
- Antibodies**, 95, 504
- Anticonvulsant drugs**, 637, 638
- Antidepressants** *Drugs that relieve depression*, 635–636, 638, 641, 642
- Antipsychotics**, *see* Neuroleptics
- Antisocial personality disorder** *A disorder involving impulsive, selfish, unscrupulous, even criminal behavior*, 554, 589–593
- Anvil**, *see* Incus
- Anxiety disorder** *A condition in which intense feelings of apprehension are long-standing or disruptive*, 557, 562, 565–571, 575, 576, 627, 628
- antidepressants for, 636, 637, 638
 - anxiolytics for, 637, 638, 640
 - biological factors in, 569, 571
 - causes of, 569–570
 - cognitive factors in, 569–570
 - depression and, 568
 - eye movement desensitization and reprocessing for, 26, 28, 30–31, 34, 37, 38, 40, 41, 42, 43, 46–47
 - generalized, 567, 575, 627, 640
 - incidence of, 554
 - learning and, 569, 570–571
 - observational learning and, 215
 - obsessive-compulsive disorder, 553, 568–569, 570, 575, 617, 627, 634, 636, 637, 640, 641
 - panic disorder, 337, 498, 560, 567–568, 569–570, 575, 604, 613, 617, 618–619, 627, 636, 637, 640, 641
 - phobias, 566–567, 569, 570–571, 575, 614, 615, 616–617, 627, 628, 637, 640
 - posttraumatic stress disorder, 72, 194, 252, 309, 322, 495–496, 568, 614, 627, 637
 - psychosurgery for, 634
 - psychotherapy for, 640, 641
 - separation, 594, 595
 - treatment of, *see* Behavior therapy
 - see also* Behavior therapy
- Anxiolytics** *Drugs that reduce feelings of anxiety*, 637
- Anxious-fearful cluster**, of personality disorders, 589, 590
- Aphasia**, 78
- Appetite**, 391
- Applied relaxation**, 627
- Approach-approach conflicts**, 411
- Approach-avoidance conflicts**, 411
- Approach-inhibition theory**, 529–530
- Aptitude tests** *Tests designed to measure a person's capacity to learn certain things or perform certain tasks*, 350
- Aricept**, 91
- Army Alpha and Beta tests**, 347–348
- Arousal** *A general level of activation that is reflected in several physiological systems and can be measured by electrical activity in the brain, heart action, muscle tension, and the state of many other organ systems*, 386–387
- aggression and, 698–701
 - altruism/helping behavior and, 703–706, 709
 - presence of other people and, 682–684
- Arousal: cost-reward theory** *A theory attributing people's helping behavior to their efforts to reduce the unpleasant arousal they feel in the face of someone's need or suffering*, 703–706, 709
- Arousal disorder**, 403

- Arousal theories** *Theories of motivation stating that people are motivated to behave in ways that maintain what is, for them, an optimal level of arousal, 386–387, 388*
- Arthritis, 95
- Artificial insemination, 478–479
- Artificial intelligence (AI)** *The field that studies how to program computers to imitate the products of human perception, understanding, and thought, 286–288*
- ASL, *see* American Sign Language
- Asperger's disorder, 595
- Assertiveness and social skills training**
Methods for teaching clients how to interact with others more comfortably and effectively, 615
- Assimilation** *The process of trying out existing schemas on objects that fit those schemas, 440–441*
- Association cortex** *Those parts of the cerebral cortex that receive information from more than one sense or combine sensory and motor information to perform such complex cognitive tasks, 76, 78–79, 81, 104*
- Associations, neural network models and, 217–218
- Associative learning, *see* Classical conditioning;
- Operant conditioning**
- Astringent, 128
- Ataques de nervios*, 559
- Attachment** *A deep and enduring relationship with the person with whom a baby has shared many experiences, 128, 453, 455–459, 478, 523*
- Attention** *The process of directing and focusing certain psychological resources to enhance information processing, performance, and mental experience, 173–178*
- aging and, 372
- automatic processing and, 177–178
- brain and, 178
- classical conditioning and, 191–192
- covert, 173, 174–175
- directing, 175
- divided, 177
- effort and, 173, 178
- ignoring, 176–177
- intelligence and, 366
- limits of, 173, 178
- mental functioning and, 173, 178
- selective, 233
- Attention deficit hyperactivity disorder (ADHD), 557, 594, 641
- Attitude** *A predisposition toward a particular cognitive, emotional, or behavioral reaction to objects, 660–665*
- affective component of, 660, 661
- behavioral component of, 660, 661
- changes in, 662–665
- cognitive component of, 660, 661
- cognitive dissonance theory and, 663–664, 665
- consistency and, 660–661
- elaboration likelihood model and, 662–663, 665
- first impressions and, 653
- formation of, 661–662
- interpersonal attraction and, 672, 673
- self-perception theory and, 664–665
- structure of, 660–661
- Attraction, *see* Interpersonal attraction
- Attribution** *The process of explaining the causes of people's behavior, including one's own, 422, 655–659*
- biases in, 657–659
- culture and, 657
- decision making and, 289, 291
- depression and, 581
- external, 655
- internal, 655
- sources of, 655–657
- Attributional biases, 657–659
- Atypical neuroleptics, *see* Neuroleptics
- Auditory cortex, 76, 109–110, 111
- Auditory nerve** *The bundle of axons that carries stimuli from the hair cells of the cochlea to the brain, 106, 107, 109, 110, 137*
- Auditory pathways, 109–111
- Auditory scene analysis** *The perceptual process through which sounds are mentally represented and interpreted, 157*
- Auditory streams, 157
- Authoritarian parents** *Firm, punitive, and unsympathetic parents who value obedience from the child and authority for themselves, 460, 461*
- obedience and, 691–692, 693
- prejudice and, 667
- Authoritative parents** *Parents who reason with the child, encourage give and take, are firm but understanding, 460–461, 462*
- Autistic disorder, 557, 594–595, 616
- biological approach to, 595, A-6
- facilitated communication for, 47, 48
- Autistic savants, 35
- Autistic spectrum disorders, 594–595
- Autoimmune disorders** *Physical problems caused when cells of the body's immune system attack normal body cells as if they were foreign invaders, 95, 504*
- Autokinetic phenomenon, 685
- Automatic thinking, 267
- Autonomic nervous system (ANS)** *A subsystem of the peripheral nervous system that carries messages between the central nervous system and the heart, lungs, and other organs and glands, 65–66, 95, 96*
- amphetamines and, 335
- antisocial personality disorder and, 590–591
- anxiety disorder and, 569
- emotion and, 415–417
- general adaptation syndrome and, 491, 492
- immune system and, 505
- nicotine and, 336
- parasympathetic system and, 65, 87, 416
- sympathetic system and, 65, 88, 416–417
- vestibular system and, 137
- Autonomy *versus* shame and doubt, 459, 460
- Availability heuristic** *A mental shortcut through which judgments are based on information that is most easily brought to mind, 278, 290*
- Aversive conditioning** *A method that uses classical conditioning to create a negative response to some stimulus, 617*
- Aversive racism, 670
- Aviation psychology, 179
- Avoidance-avoidance conflicts, 411
- Avoidance conditioning** *A type of learning in which an organism responds to a signal in a way that avoids exposure to an aversive stimulus, 198–199, 209*
- Avoidant attachment, 523
- Avoidant personality disorder, 589, 590
- Axons** *Fibers that carry signals from the cell body of a neuron out to where communication occurs with other neurons, 58, 59, 60, 61, 63, 82*
- Babblings** *The first sounds infants make that resemble speech, 297*
- Backward conditioning, 191
- Balance, 131, 137
- Balanced bilinguals, 300
- Barbiturates, 333, 334–335
- Bargaining, conflict management and, 713
- BAS, *see* Behavioral approach system
- Base rates, 278
- Basilar membrane** *The floor of the fluid-filled duct that runs through the cochlea, 106, 107, 108, 109, 110*
- B-cells, 504, 505
- Bedlam, 557
- Behavior**
- evolutionary approach to, 17
- genetics and, A-5–A-6
- subliminal stimuli and, 147–149
- Behavioral approach** *An approach to psychology emphasizing that human behavior is determined mainly by what a person has learned, especially from rewards and punishments the person has experienced in interacting with other people; also called behavioral model, 18, 20, 613*
- classical and operant conditioning and, 208–209
- to motivation, 382
- see also* Behavior therapy
- Behavioral approach system (BAS)** *Brain regions that affect people's sensitivity to rewards, 530*
- Behavioral coping strategies, 514
- Behavioral dependence, 595
- Behavioral genetics** *The study of the effect of genes on behavior, A-1–A-9*
- adoption studies in, 51–52, A-3
- environment and, A-6–A-8
- family studies in, 50, 51, A-3
- Human Genome Project and, 52, A-6
- research and, 49–52, A-3–A-4
- see also* Genetics
- Behavioral inhibition system (BIS)** *Brain regions that affect people's sensitivity to punishment, 530*
- Behavioral premarital intervention, 623
- Behavioral stress responses, 488, 494–496, 503
- Behaviorism, 14, 15, 18, 309, A-3

- Behavior modification** *Treatments that use operant conditioning methods to change behavior*, 613, 614–618, 622
- Behavior therapy** *Treatments that use classical conditioning principles to change behavior*, 613–620, 622
- aversive conditioning, 617
 - behavior modification, 613, 614–618, 622
 - cognitive-behavior therapy, 614, 618–620, 622, 625, 626–628, 640
 - cognitive therapy, 619–620, 626–628, 641
 - effectiveness of, 625, 626–628
 - extinction, 616–617
 - modeling, 615
 - positive reinforcement, 615–616
 - punishment, 617–618
 - rational-emotive behavior therapy, 618–619
 - systematic desensitization, 614–615
- Bell Curve, The*, A-3–A-4
- Belongingness motives, 409, 410
- Benzodiazepines, 637, 638, 639, 641
- Beta-amyloid, 73–75
- Beta-amyloid precursor protein, 73–75
- Bias(es)
- in attribution, 657–659
 - confirmation, 30, 276, 284, 285, 292
 - in decision making, 289–291, 292
 - experimenter, 40–41
 - in IQ tests, 354–356, 358–361, 363
 - in psychological diagnosis, 563–565
 - in sampling, 32
- Biased sample** *A group of research participants selected from a population each of whose members did not have an equal chance of being chosen*, 32
- Big-five model** *Five trait dimensions found in many factor-analytic studies of personality: neuroticism, extraversion, openness to experience, agreeableness, and conscientiousness*, 526–528, 532, 533
- Bilingualism, 300–301
- Binocular disparity** *A depth cue based on the difference between two retinal images of the world*, 160, 161
- Biological approach** *An approach to psychology in which behavior and behavior disorders are seen as the result of physical processes, especially those relating to the brain and to hormones and other chemicals; also called biological model*, 16–17, 20, 56
- to aggression, 695–696
 - to anxiety disorder, 569
 - to arousal, 386
 - to autistic disorder, 595, A-6
 - to eating, 388–389
 - to emotion, 413–417, 418, 421–422, 423–424
 - to hunger, 395
 - to incentives, 387
 - to language acquisition, 299–300
 - to memory, 253–258, A-6
 - to mood disorder, 579–580, 582
 - to motivation, 382
 - to prejudice/stereotypes, 666
 - to psychological disorders, 556–557, 641–642
 - to reinforcement, 204–205
 - to schizophrenia, 586–588, A-6–A-7
 - to sexual behavior, 398–399
 - to sexual orientation, 400–403
 - social cognitive neuroscience and, 665–666
 - trait theories and, 526, 527, 533
 - see also* Biology; Genetics; Nature and nurture
- Biological clock, 580
- Biological motives, 409, 410
- Biological preparedness, 571
- Biological psychologists** *Psychologists who analyze the biological factors influencing behavior and mental processes; also called physiological psychologists*, 3, 8, 9
- Biological psychology** *The psychological specialty that researches the physical and chemical changes that cause, and occur in response to, behavior and mental processes*, 55
- Biological rhythms, 71
- Biological treatments, 632–634
- electroconvulsive therapy, 633–634, 639
 - psychosurgery, 634, 639
 - see also* Psychoactive drugs
- Biology, 54–55. *See also* Biological approach; Endocrine system; Genetics; Immune system; Nervous system; Sensory systems
- Biopreparedness, 192–193
- Biopsychosocial model** *A view of mental disorders as caused by a combination of interacting biological, psychological, and sociocultural factors*, 556–559, 560
- alcohol use disorders and, 596
 - antisocial personality disorder and, 591
- Biotechnology, 14
- Bipolar cells, 114, 116
- Bipolar disorders, 557, 578–579, 580
- lithium and anticonvulsants for, 636–637, 638
- Bipolar I disorder** *A condition in which a person alternates between deep depression and mania*, 578
- Bipolar II disorder, 578
- BIS, *see* Behavioral inhibition system
- Bisexual** *People who engage in sexual activities with partners of both sexes*, 400, 401, 402–403
- Blindness, 138
- hypnosis and, 328
 - touch and, 131
- Blindsight, 312
- Blind spot** *The light insensitive point at which axons from all of the ganglion cells converge and exit the eyeball*, 116, 118
- Blood, hunger and, 389, 391, 393, 395
- Blood-brain barrier** *A feature of blood vessels supplying the brain that allows only certain substances to leave the blood and interact with brain tissue*, 331
- BMI (body-mass index), 392
- Body-kinesthetic intelligence, 369–370
- Body language, in Gestalt therapy, 612
- Bone marrow, 95
- Borderline personality disorder, 589, 590
- Bottom-up processing** *Aspects of recognition that depend first on the information about the stimulus that comes up to the brain from the sensory receptors*, 165–168, 169, 171, 295
- Braille, 131
- Brain, 55, 64, 66, 68–86, 114
- acupuncture and, 69
 - addicts and, 332
 - in adulthood, 84–86, 370–372, 440, 471, 474–477, 480, 481
 - aggression and, 695–696
 - alcohol consumption and, 596, 597
 - analogies and, 281–282
 - antisocial personality disorder and, 590
 - association cortex and, 76, 78–79, 81, 104
 - attention and, 178
 - autistic disorder and, 595
 - autonomic nervous system and, 65
 - cells of, 57
 - corpus callosum and, 79, 81–82, 86
 - decision making and, 269
 - dreams and, 326
 - electroconvulsive therapy and, 633–634, 639
 - emotion and, 414–415, 418, 421–422, 423–424
 - forebrain and, 70, 71–73, 86, 87, 88
 - functions of, 56, 63
 - general adaptation syndrome and, 491–492
 - hearing and, 109–110
 - hemispheres of, 75, 79–82
 - hindbrain and, 68–71, 86, 88
 - hormones and, 94–95
 - human development and, 84–86
 - hunger and, 389, 390–391, 393, 394, 395
 - immune system and, 505
 - in infancy, 437, 438, 439
 - information-processing tasks of, 60
 - intelligence and, 366, 367, 369
 - kinesthesia and, 137–138
 - language and, 111
 - lateralization of, 80–82
 - learning disabilities and, 377
 - locus coeruleus and, 69–70, 88, 325, 334
 - memory and, 253–258
 - midbrain and, 70, 71, 86, 87, 88
 - motor cortex and, 76, 77–78
 - neural networks in, 62
 - neuropsychology and, 34–35
 - of newborn, 437
 - number of cells in, 70
 - olfaction and, 127
 - pain and, 133–135
 - parallel distributed processing and, 66
 - plasticity of, 82–86
 - prejudice/stereotypes and, 666
 - problem solving and, 269
 - psychosurgery and, 634, 639
 - recognition and, 166–167
 - reinforcement and, 204–205
 - retrieval and, 257–258
 - schizophrenia and, 584, 586–588
 - sensory cortex and, 76–77, 102, 103
 - sensory system and, 101, 102, 103–104, 110, 113
 - sexual behavior and, 398
 - sexual orientation and, 401
 - sleep and, 323, 324, 325
 - somatosensory cortex and, 76, 77, 138
 - spinal cord and, 67

- split-brain studies and, 79–80
 techniques for studying, *see* Neuroimaging
 vestibular sense and, 131, 137
 vision and, 113, 116–117, 118–119, 120
see also Cerebellum; Cerebral cortex;
 Cognitive development; Consciousness;
 Electroencephalograph; Hippocampus;
 Hypothalamus; Intelligence;
 Neurotransmitters; Psychoactive drugs;
 Thalamus
- Brain damage**
 consciousness and, 315–317
 dementia and, 73, 556–557, 562, *see also*
 Alzheimer's disease
 emotion and, 414–415
 epilepsy and, 89
 gender differences in, 81
 Huntington's disease and, 88–89, A-5
 Korsakoff's syndrome and, 256–257
 language and, 78–79
 memory and, 255–257
 multiple sclerosis and, 59
 nootropic drugs and, 90–92
 olfactory neuron regeneration and, 126
 Parkinson's disease and, 83, 84, 88
 prosopagnosia and, 316–317
 split-brain patients and, 79–80
 strokes and, 89, 138
 synaptic plasticity and, 82–84
 vision and, 119
see also Amnesia
- Brainstorming**, 292
- Brain surgery**, *see* Psychosurgery
- Brain waves**, 330. *See also*
 Electroencephalograph
- Brightness** *The overall intensity of all of the wavelengths that make up light*, 120, 121
- Brightness constancy**, 164–165
- Broca's aphasia**, 78
- Broca's area**, 76, 78, 79
- Brown-Peterson procedure** *A method for determining how long unrehearsed information remains in short-term memory*, 236
- BSTc**, 398
- Bulimia nervosa** *An eating disorder that involves eating massive quantities of food and then eliminating the food by self-induced vomiting or the use of strong laxatives*, 394–395, 628
- Buprenorphine**, 336
- Bupropion (Wellbutrin)**, 636
- Burnout** *A gradually intensifying pattern of physical, psychological, and behavioral dysfunctions in response to a continuous flow of stressors*, 495, 496
- Bupirone (BuSpar)**, 637, 638
- Bystander effect**, 704
- Caffeine**, 330, 336
- Cannabis**, *see* Marijuana
- Cannon-Bard theory**, 418, 421–422, 423
- Capsaicin**, 130, 132–133, 134
- Captainitis**, 692
- Carbolith**, *see* Lithium
- Carbon monoxide**, as neurotransmitter, 89
- Case study** *A research method involving the intensive examination of some phenomenon in a particular individual, group, or situation. It is especially useful for studying complex or relatively rare phenomena*, 31, 34–35, 42, 139–140, 314–315
- Catabolic effects**, 390
- Catastrophic events**, as stressors, 488, 489
- Catastrophizing**, 493–494, 513
- Catecholamines**, 87–88, 491, 507
- Cause-and-effect relationships**, 31, 37
- CCK**, *see* Cholecystokinin
- Cell assembly**, 254
- Cell body**, of neuron, 57
- Cell division**, A-1–A-2
- Cell phones**, driving and, 180–181
- Center-off ganglion cells**, 116
- Center-on ganglion cells**, 116, 117
- Center-surround receptive fields**, 116, 117, 119
- Central nervous system (CNS)** *The part of the nervous system encased in bone, including the brain and the spinal cord*, 66–86
 antisocial personality disorder and, 590–591
 depressants and, 332, 333–335, 339
 function of, 66–67
 neural networks and, 66
 nuclei of, 66
 synaptic plasticity and, 82–84
see also Brain; Nervous system; Spinal cord
- Central route**, in elaboration likelihood model, 662, 663
- Central tendency**, measures of, 42–44, A-11
- Central theory**, *see* Cannon-Bard theory
- Central traits**, 526
- Cerebellum** *The part of the hindbrain whose function is to control finely coordinated movements and to store learned associations that involve movement*, 70–71, 86
 alcohol and, 334
 vestibular system and, 137, 138
- Cerebral cortex** *The outer surface of the brain*, 70, 72, 75–79, 84–85, 86, 87, 88, 89, 102, 103–104
 alcohol and, 334
 emotion and, 414–415
 memory and, 255
 pain and, 133
 sensory systems and, 102, 103–104
- Cerebral hemispheres** *The left and right halves of the rounded, outermost part of the brain*, 75
- C fibers**, 133
- Challenger**, 715
- Channels**, acupuncture and, 135–136
- Chaos theory**, 9
- Characteristic frequency**, 108
- Chemical senses**, *see* Gustation; Olfaction
- Child abuse**, 620
 antisocial personality disorder and, 591–593
 classical psychoanalysis and, 606–607
 depression and, 581
 dissociative disorders and, 574
 pornography and, 699
- Childhood**
 altruism/helping behavior in, 703
 attitude formation in, 661–662
 cognitive development in, 440, 441, 445–450, 447
 gender roles in, 464–466
- information processing in, 447–449
 latency period in, 522
 memory in, 447–450
 moral reasoning in, 472–473
 peer relationships in, 461–463
 phallic stage in, 521–522
 psychological disorders in, 562, 593–595
 risk and resilience in, 466–467
 social and emotional development in, 457, 459–467, 480
 social skills in, 463–464
 temperament in, 543–545
- Chinese Psychiatric Association**, 400
- Chlordiazepoxide (Librium)**, 637, 638
- Chlorpromazine (Thorazine; Largactil)**, 635, 638
- Cholecystokinin (CCK)**, 389, 395
- Cholesterol**, 507
- Cholinergic neurons**, 87
- Chromosomes** *Long, thin structures in every biological cell that contain genetic information*, A-1–A-2
- Chronic stressors**, 488
- Chronological age**, 346
- Chunks** *Stimuli that are perceived as one unit or a meaningful grouping of information*, 235–236, 261, 285
- Cingulate cortex**, 133, 134
- Circadian rhythm** *A cycle, such as waking and sleeping, that repeats about once a day*, 323, 324
- Circle of thought**, 266–267, 279
- Civil disobedience**, 692
- Clang associations**, schizophrenia and, 583
- Clarity**
 depth cues and, 159, 160
 as MDMA, 337
- Classical conditioning** *A procedure in which a neutral stimulus is paired with a stimulus that elicits a reflex or other response until the neutral stimulus alone comes to elicit a similar response*, 14, 187–195
 acquisition and, 187–188, 194
 Alzheimer's disease and, 194–195
 attention and, 191–192
 attitudes and, 661–662
 avoidance conditioning and, 198
 behavioral approach to, 208–209
 biopreparedness and, 192–193
 extinction and, 189, 190, 194
 Pavlov's discovery and, 187–188
 phobias and, 5, 193–194, 570–571
 predator control and, 194, 195
 predictability and, 191
 second-order conditioning and, 192
 signaling of significant events and, 190–193
 signal strength and, 191
 spontaneous recovery and, 189, 190
 stimulus generalization and discrimination and, 190, 194
 timing and, 191
see also Behavior therapy
- Claustrophobia**, 566
- Client-centered therapy (person-centered therapy)** *A therapy that allows the client to decide what to talk about, without direction*,

- judgment, or interpretation from the therapist*, 540, 610–612
- Client-therapist relationships, *see* Therapeutic relationship
- Clinical psychologists** *Psychologists who seek to assess, understand, and correct abnormal behavior*, 5, 8
- Clinical social workers, 606
- Clomipramine (Anafranil), 633, 636, 637, 642
- Clonazepam (Klonopin), 637, 638
- Cloning, animals and, 39
- Closure, as Gestalt law, 155, 156, 157
- Clozapine (Clozaril), 635, 638, 640
- CNS, *see* **Central nervous system**
- Cocaine, 88, 205, 332, 335–336, 436, 597–598, 627
- Cocaine babies, 336
- Cochlea** *A fluid-filled spiral structure in the ear in which auditory transduction occurs*, 106, 107–108
- Cochlear implants, 107
- Coding** *Translating the physical properties of a stimulus into a pattern of neural activity that specifically identifies those properties*, 101, 102
- hearing and, 108–110
- kinesthesia and, 138–140
- touch and, 132
- Cognition, learning and, 208–218. *See also* **Social cognition**
- Cognitive ability** *The capacity to reason, remember, understand, solve problems, and make decisions*, 345–346
- creativity and, 373–374
- giftedness and, 374–375
- learning disabilities and, 376–377
- mental retardation and, 375–376
- over life span, 370–372
- parental responsiveness and, 452, A-8
- see also* **Intelligence; Intelligence quotient; IQ test**
- Cognitive/affective theory, 535–536
- Cognitive appraisal theories, 423, 424
- Cognitive approach** *A way of looking at human behavior that emphasizes research on how the brain takes in information, creates perceptions, forms and retrieves memories, processes information, and generates integrated patterns of action*, 18–19, 20
- to anxiety disorder, 569–570
- to attitudes, 661
- to emotion, 418, 422–423

- Genital stage** *The last of Freud's psychosexual stages, which begins during adolescence when sexual impulses appear at the conscious level, 522*
- Genius, A-3
- Genotype** *The full set of genes, inherited from both parents, contained in twenty-three pairs of chromosomes, A-2*
- Geons, 167, 168
- Gephyrophobia, 566
- German measles (rubella), 375, 436
- Germinal stage, 435
- Gestalt laws, 155, 156, 157
 social perception and, 652
- Gestalt psychologists, 12, 15, 155, 212
- Gestalt therapy** *An active treatment designed to help client's get in touch with genuine feelings and to disown foreign ones, 610, 612–613*
- Giftedness, 374–375, 452
- Ginkgo biloba, 90, 91
- Glands** *Organs that secrete hormones into the bloodstream, 92–95*
- Glial cell line-derived neurotrophic factor (GDNF), 83
- Glial cells** *Cells in the nervous system that hold neurons together and help them communicate with one another, 58, 82*
- Glove anesthesia, 573
- Glucose, 389
- Glutamate** *An excitatory neurotransmitter that helps strengthen synaptic connections between neurons, 89, 91, 255, 333, 336, 587*
- Glutamate receptor, 337
- Goal setting, achievement motivation and, 406–407
- Graduate Records Examination (GRE), 350
- Grammar** *A set of rules for combining the words used in a given language, 293, 294, 298, 299*
- Grandparenthood, 480
- Grasping reflex, 438
- GRE, *see* Graduate Records Examination
- Greeneville, USS, 692
- Group assertiveness training, 615
- Group identity, *see* Social identity
- Grouping, perceptual organization and, 154, 155–157, 164
- Group polarization, 292
- Group processes, 714–716
 groupthink and, 715–716
 leadership and, 714–715
 problem solving and decision making and, 291–292
 social loafing and, 683–684
- Group therapy** *Psychotherapy involving several unrelated clients, 605, 620–621, 629*
- Groupthink** *A pattern of thinking in which group members fail to evaluate realistically the wisdom of various options and decisions, 715–716*
- Growth factors
 brain-tissue grafts and, 83
 hair cell regeneration and, 107
- Growth orientation** *According to Maslow, drawing satisfaction from what is available in life, rather than focusing on what is missing, 540*
- Growth theory, 540, 541
- GSR, *see* Galvanic skin resistance
- Guilty but mentally ill, 600
- Gustation** *The sense that detects chemicals in solutions that come into contact with receptors inside the mouth; the sense of taste, 128–130*
 absolute thresholds and, 146
 in newborn, 437, 438
 taste aversions and, 193
- Gyri, 75, 76
- Habituation** *The process of adapting to stimuli that do not change, 171*
 fetus and, 435
 learning and, 186
 psychoactive drugs and, 186–187
- Hair cells, of organ of Corti, 106, 107, 108, 110
- Hallucinations** *A symptom of disorder in which people perceive voices or other stimuli when there are no stimuli present, 317, 326, 583–584*
- Hallucinogens** *Psychoactive drugs that alter consciousness by producing a temporary loss of contact with reality and changes in emotion, perception, and thought, 332, 337–341, 391*
- Haloperidol (Haldol), 635, 638, 641–642
- Hammer, *see* Malleus
- Happiness, 412
 subjective well-being and, 408–409

- analysis of variance and, A-17–A-18
- statistically significant and, 46, 47, A-15
- t* test and, A-15–A-16
- Inflections, 299

- Informal reasoning** *The process of evaluating a conclusion, theory, or course of action on the basis of the believability of evidence, 276–278*
- Information processing, 14**
 in childhood, 447–449
 cognitive approach to, 19
 in late adulthood, 372
 learning disabilities and, 377
 without awareness, 312
- Information-processing approach** *An approach to the study of intelligence that focuses on mental operations, such as attention and memory, that underlie intelligent behavior, 366, 367, 369*
- Information-processing model** *A model of memory in which information is seen as passing through sensory memory, short-term/working memory, and long-term memory, 231–232*
 of thought, 266–267, 270, 274
see also Long-term memory; Sensory memory; Short-term memory
- Information-processing system** *Mechanisms for receiving, mentally representing, and manipulating information, 266–267*
 measurement of, 267–269
- In-group**
 prejudice and, 667
 ultimate attribute error and, 658
- Inhibitory postsynaptic potential (IPSP)** *A postsynaptic potential that hyperpolarizes the neuronal membrane, making a cell less likely to fire an action potential, 61*
- Initiative versus guilt, 460**
- Injunctive norms, 680–681**
- Inpatients, 604–605**
- Insanity, 599–600**
- Insanity Defense Reform Act, 599**
- Insecure attachment, 457, 458–459, 478, 523**
- Insight** *In problem solving, a sudden understanding about what is required to produce a desired effect, 212–213*
- Insomnia** *A sleep disorder in which a person feels tired during the day because of trouble falling asleep or staying asleep at night, 208, 320–321*
- Instincts** *Innate, automatic dispositions toward responding in a particular way when confronted with a specific stimulus; instincts produce behavior over which an organism has no control, 383, 519–520*
- Instinct theory** *A view that explains human behavior as motivated by automatic, involuntary, and unlearned responses, 383–385, 388*
- Instrumental conditioning** *A process through which responses are learned that help produce some rewarding or desired effect, 196–197. See also* Operant conditioning
- Insulin, 389, 390, 395**
- Integrity versus despair, 460, 481**
- Intelligence** *Those attributes that center around reasoning skills, knowledge of one's culture, and the ability to arrive at innovative solutions to problems, 346, 365–370*
 analytic, 366, 367, 368
 creativity and, 366–367, 368, 374

steps in, 282, 287
strategies for, 279–282
working backward and, 279–280
- Problem-solving therapy, 627
- Procedural memory** *A type of memory containing information about how to do things*, 226, 227, 256
- Profound mental retardation, 375
- Progesterone, 398, 474
- Progestins** *Feminine hormones that circulate in the bloodstream of both men and women; relatively more progestins circulate in women*, 398
- Progressive relaxation training** *A procedure for learning to relax that involves tensing then releasing muscles*, 514, 614
- Projection, 521
- Projective tests** *Personality tests made up of unstructured stimuli that can be perceived and responded to in many ways*, 524, 548–549
- Propositions** *Mental representations of the relationship between concepts*, 271, 275
- Proprioceptive senses** *The sensory systems that allow us to know about where we are and what each part of our body is doing*, 137–140
kinesthesia and, 131, 137–140
vestibular system and, 131, 137
- Prosopagnosia, 316–317
- Prospective research design, 591–593
- Prototype** *A member of a natural concept that possesses all or most of its characteristic features*, 271
- Proximity
as Gestalt law, 155, 156
interpersonal attraction and, 672
and obedience, 691
- Prozac, *see* **Fluoxetine**

- Psyche, 558
- Psychedelics, *see* **Hallucinogens**
- Psychiatric nurses, 606
- Psychiatrists** *Medical doctors who have completed special training in the treatment of mental disorders*, 605, 639, 640. *See also* **Psychoactive drugs**
- Psychiatry, 633
- Psychic energy, 520
- Psychoactive drugs** *Substances that act on the brain to create some psychological effect*, 87, 317, 330–341, 632
- aggression and, 696
 - antidepressants, 635–636, 638, 641, 642
 - anxiolytics, 637, 638, 639, 640, 641
 - cocaine, 88, 205, 332, 335–336, 436, 597–598, 627
 - depressants, 332, 333–335, 339
 - evaluation of for treatment, 639–640
 - expectations and effects of, 332–333, 334
 - habituation and, 186–187
 - hallucinogens, 332, 337–341, 391
 - heroin, 89, 186, 332, 337, 597–598, 696
 - human diversity and, 637–639
 - lithium and anticonvulsants, 636–637
 - neuroleptics, 635, 638, 639, 640, 641–642
 - neurotransmitters and, 641–642
 - opiates, 89–90, 332, 337, 338, 339, 627, 696
 - prenatal development and, 336, 436, 598
 - psychiatrists and, 605, 639, 640
 - psychopharmacology of, 330–331
 - psychotherapy and, 604, 640–641
 - stimulants, 330, 332, 335–337, 339, 386, 696
 - substance-related disorders and, 554, 595–598
 - therapeutic, 634–642
 - tranquilizers, 696
 - varying effects of, 331–333
- see also specific drugs*
- Psychoanalysis** *A method of psychotherapy that seeks to help clients gain insight by recognizing and understanding unconscious thoughts and emotions*, 12–13, 15, 31
- case studies in, 34
 - classical, 606–608, 622
 - contemporary, 607–609, 622, 627
 - dreams and, 326
 - unconscious and, 313, 326, 606–608, 622
- Psychoanalytically oriented psychotherapy, 609
- Psychobiological models, 493
- Psychodynamic approach** *A view developed by Freud that emphasizes the interplay of unconscious mental processes in determining human thought, feelings, behavior, and personality; also called psychodynamic model*, 18, 20, 519–525, 541
- conflicts and defenses and, 520, 521, 524
 - to depression, 581
 - to dissociative disorders, 574
 - evaluation of, 523–525
 - id, ego, and superego and, 520
 - neo-Freudian theorists and, 522–523, 524
 - object relations and, 523
 - to psychological disorders, 558, 560
 - social-cognitive approach to, 537
 - stages in personality development and, 520–522
 - structure and development of personality and, 519–522
 - see also* **Psychoanalysis**; **Psychodynamic psychotherapy**
- Psychodynamic model, *see* **Psychodynamic approach**
- Psychodynamic psychotherapy, 606–609, 622
- classical psychoanalysis, 606–608, 622
 - contemporary, 607–609, 622, 627
 - effectiveness of, 625
- Psychological dependence** *A condition in which a person uses a drug despite adverse effects, needs the drug for a sense of well-being, and becomes preoccupied with obtaining it*, 332, 595. *See also* **Psychoactive drugs**
- Psychological disorders, 552–602
- abnormality and, 554–555, 556
 - biological factors in, 641–642
 - biopsychosocial model of, 556–559, 560
 - of childhood, 562, 593–595
 - classification of, 532, 560–561, *see also* *Diagnostic and Statistical Manual of Mental Disorders*
 - costs of, 553
 - criminal justice and, 598–600
 - cultural differences in, 555, 556, 557, 558–559
 - definition of, 554–555
 - desensitization and, 194
 - diagnosis of, 561–565, *see also* **Personality tests**
 - diathesis-stress approach to, 559, 560
 - dissociative disorders, 562, 573–575
 - earliest explanations of, 554
 - explanation of, 554–560
 - incidence of, 554
 - medical model of, 530, 556, 563
 - neurobiological model of, 556, 560
 - practical approach to, 555
 - prevalence of, 553
 - psychological model of, 557–558, 560
 - sociocultural model of, 559–560
 - somatoform disorders, 562, 572–573, 575
 - stress and, 495–496
 - substance-abuse disorders, 562
 - substance-related disorders, 554, 595–598
 - supernatural explanations of, 556, 557
 - see also* **Anxiety disorder**; **Mood disorder**; **Personality disorders**; **Schizophrenia**; **Treatment, of psychological disorders**
- Psychological model** *A view in which mental disorder is seen as arising from inner turmoil or other psychological processes*, 557–558, 560
- Psychological stressors, 488–489
- Psychologists** *Among therapists, those whose education includes completion of a master's or doctoral degree in clinical or counseling psychology, often followed by additional specialty training*, 605–606. *See also* **Psychotherapy**
- Psychology** *The science of behavior and mental processes*
- and academic disciplines, 8–9
 - approaches to, 16–21, *see also* **Behavioral approach**; **Biological approach**; **Cognitive approach**; **Evolutionary approach**; **Humanistic approach**; **Psychodynamic approach**
 - cultural differences and, 21–23
 - current status of, 14–15
 - definition of, 2–3, 15
 - history of, 11–14, 15
 - subfields of, 3–9
 - unity in, 15
 - women and minorities in, 15, 16, 17
- Psychometric approach** *A way of studying intelligence that emphasizes analysis of the products of intelligence, especially scores on intelligence tests*, 365–366, 369
- Psychoneuroimmunology** *The field that examines the interaction of psychological and physiological processes that affect the ability of the body to defend itself against disease*, 504, 506
- Psychopathology** *Patterns of thinking and behaving that are maladaptive, disruptive, or uncomfortable for the person affected or for those with whom he or she comes in contact*, 523. *See also* **Psychological disorders**
- Psychopaths, 589–590. *See also* **Antisocial personality disorder**
- Psychopharmacology** *The study of psychoactive drugs and their effects*, 330–331. *See also* **Psychoactive drugs**
- Psychophysics** *An area of research focusing on the relationship between the physical characteristics of environmental stimuli and the psychological experience those stimuli produce*, 11, 146–154
- absolute thresholds and, 146, 147–149
 - judging differences and, 152
 - magnitude estimation and, 153–154
 - signal-detection theory and, 146, 149–152
 - subliminal stimuli and, 147–149
 - supraliminal stimuli and, 147, 148
- Psychosexual stages** *In Freud's psychodynamic theory, periods of personality development in which conflicts focus on particular issues*, 520–521
- Psychosis, 561
- Psychosocial development, 459, 460, 470–471, 478, 479–480, 481, 542
- Psychosocial rehabilitation, 642
- Psychosurgery** *Surgical procedures that destroy tissue in small regions of the brain in an effort to treat psychological disorders*, 634, 639
- Psychotherapy** *The treatment of psychological disorders through talking and other psychological methods*, 604
- beginnings of, 606
 - cultural factors in, 629–631
 - drug therapy with, 604, 640–641, *see also* **Psychoactive drugs**
 - empirically supported therapies and, 626–628
 - evaluation of, 623–632
 - inpatients and, 604–605
 - outpatients and, 605
 - providers of therapy and, 605–606

- therapeutic relationship in, 613, 628–629, 631–632
see also Behavior therapy; Couples therapy; Family therapy; Group therapy; Humanistic psychotherapy; Psychodynamic psychotherapy
- Psychoticism, 529
- Psychotomimetics, *see* Hallucinogens
- PTSD, *see* Posttraumatic stress disorder
- Puberty *The condition of being able for the first time to reproduce*, 398, 467–469
- Public conformity, 685
- Public goods dilemma, 712
- Punishment** *The presentation of an aversive stimulus or the removal of a pleasant stimulus; punishment decreases the frequency of the immediately preceding response; in therapy, weakening undesirable behavior by following it with an unpleasant stimulus*, 205–208
 aggression and, 697
 in behavior therapy, 617–618
 discipline and, 461
- Pupil** *An opening in the eye, just behind the cornea, through which light passes*, 112, 113
- Puzzle box, 195–196, 197
- Pyramidal motor system, 414
- Pyridoxine, *see* Vitamin B6
- Quetiapine (Seroquel), 635
- r*, *see* Pearson product-moment correlation
- Rainbow, 120
- Rain Man*, 35
- Random assignment** *The procedure by which random variables are evenly distributed in an experiment by putting participants into various groups by means of a coin flip or other random process*, 39
- Random sample** *A group of research participants selected from a population in which all members had an equal chance of being chosen for study*, 32, 39
- Random variables** *In an experiment, confounding variables in which uncontrolled or uncontrollable factors affect the dependent variable along with or instead of the independent variable*, 39
- Range** *A measure of variability that is the difference between the highest and the lowest value in a data set*, 44, 46, A-11–A-12
- Range theory, hunger and, 390
- Rape, pornography and, 699–701
- Rapid eye movement (REM) sleep** *A stage of sleep in which EEG and other functions resemble the waking state, but is accompanied by rapid eye movements and virtual muscle paralysis*, 319–320, 321, 322, 325, 326
- Rational-emotive therapy (REBT)** *A treatment designed to identify and change self-defeating thoughts that lead to anxiety and other symptoms of disorder*, 618–619
- Rationalization, 521
- Reaction formation, 521
- Reaction time** *The time between the presentation of a stimulus and an overt response to it*, 267–268
- Readiness to change health behaviors, 511–512
- Reality principle** *According to Freud, the operating principle of the ego that creates compromises between the id's demands and those of the real world*, 520
- Reasoning** *The process by which people evaluate and generate arguments and reach conclusions*, 274–278
 anchoring heuristic and, 277–278
 availability heuristic and, 278
 deductive, 274–275
 formal, 274–276
 informal, 276–278
 language and, 304–305
 representativeness heuristic and, 278
- REBT, *see* Rational-emotive behavior therapy
- Recall, 226, 238–239. *See also* Retrieval
- Recency effect** *A characteristic of memory in which recall is particularly good for the last few items on a list*, 239
- Receptive field** *The portion of the world that affects a given sensory neuron*, 116
- Receptors** *Sites on the surface of cells that allow only one type of neurotransmitter to fit into them, triggering a chemical response that may lead to an action potential*, 60, 62, 63
 psychoactive drugs and, 330–331
- Recessive genes, A-2
- Reciprocal determinism, 534–535, 544–545
- Reciprocal teaching, 219
- Reciprocity, 681
- Recognition, 165–171, 226
 bottom-up processing and, 165–168, 169, 171
 network processing and, 170–171
 top-down processing and, 165, 168–170, 169, 171
see also Retrieval
- Reconditioning** *The relearning of a conditioned response following extinction*, 189
- Reference groups** *Categories of people to which people compare themselves*, 648
- Reflection** *An active listening method in which a therapist conveys empathy by paraphrasing clients' statements and noting accompanying feelings*, 611, 612
- Reflexes** *Involuntary, unlearned reactions in the form of swift, automatic, and finely coordinated movements in response to external stimuli*, 67, 71, 188
 in adulthood, 474–475
 in newborn, 438, 448
 vestibular, 137
- Refractory period** *A short rest period between action potentials*, 60
- Refractory phase, of sexual response cycle, 399
- Rehabilitative medicine, proprioception and, 138
- Rehearsal, 248
 memory and, 229–230
- Reinforcement/reinforcer** *A stimulus event that increases the probability that the response that immediately preceded it will occur again*, 201
 accidental, 204
 continuous, 202
 delay and size of, 201–202
 explanation for, 204–205
 extinction and, 203–204, 208
 negative, 197, 198, 207
 partial, 202–204
 positive, 197, 198, 207, 208
 primary, 201, 204
 schedules of, 202–204
 secondary, 201, 204
 shaping and, 200–201
- Relapse prevention therapy, 627
- Relative deprivation** *The belief that one is not doing as well as others in one's reference group*, 648
- Relative size** *A depth cue whereby larger objects are perceived as closer than smaller ones*, 158, 159
- Relaxation
 applied, 627
 progressive relaxation training and, 514, 614
- Reliability** *The degree to which a test can be repeated with the same results*, 30, 351
 interrater, 563
 of IQ tests, 352–353
 of personality tests, 545
- Reliability Scale, 518
- REM behavior disorder** *A sleep disorder in which a person does not lose muscle tone during REM sleep, allowing the person to act out dreams*, 322
- REM sleep, *see* Rapid eye movement (REM) sleep
- Repetition, memory and, 259
- Repetitive transcranial magnetic stimulation (rTMS), 633
- Representation
 sensory systems and, 103–104, 109–111
 visual, 117–120
- Representativeness heuristic** *A mental shortcut that involves judging whether something belongs in a given class on the basis of its similarity to other members of that class*, 278
- Representative sample, 32
- Repression, 521
 traumatic memories and, 250–253
- Reproduction, A-1–A-2
 pheromones and, 128
- Research methods, 9–11, 31–53
 adoption studies and, 51–52, A-3
 analogue, 707–709
 behavioral genetics and, 49–52, A-3–A-4
 case studies and, 31, 34–35, 42, 139–140, 314–315
 control in, 33, 38, 39, 41, 74, 91, 592–593
 critical thinking and, 26–31, 47–48
 cross-sectional studies and, 370
 cross-sequential with resampling design and, 371
 data in, 30, *see also* Descriptive statistics; Inferential statistics
 ethics and, 39, 48–49

 goals in, 31–32, 33
 hypothesis in, 29–30
 longitudinal studies and, 370–371, 501–503, 543–545
 naturalistic observation and, 31, 33–34, 42
 neuroimaging and, 280–282
 prospective research design and, 591–593

- sampling and, 32–33, 39
 social impact of, 47, 48
 surveys and, 31, 35–36, 42, 396–398
 theories and, 30–31
 twin studies and, 50–51, A-3
 variables in, 30, 38–41
see also Animal studies; Experiments; Statistics
- Resilience** *A quality allowing children to develop normally in spite of severe environmental risk factors, 466–467*
- Resistance stage, general adaptation syndrome and, 492
- Resolution phase, of sexual response cycle, 399
- Resource dilemma** *A situation in which people must share a common resource, creating conflicts between the short-term interests of individuals and the long-term interests of the group, 712*
- Response**
 conditioned, 188, 189–190, 191, 198
 unconditioned, 188, 189, 191
- Response criterion** *The internal rule a person uses to decide whether or not to report a stimulus, 150, 151, 152*
- Reticular formation** *A network of cells and fibers threaded throughout the hindbrain and midbrain that alters the activity of the rest of the brain, 69, 70, 86*
- Retina** *The surface at the back of the eye onto which the lens focuses light rays, 112, 113, 114–117, 118, 160, 161*
- Retirement, 480–481
- Retrieval** *The process of recalling information stored in memory, 226, 239–253*
 brain and, 257–258
 constructive memory and, 242, 243–247, 257
 context and state dependence and, 240
 encoding specificity and, 239, 240
 eyewitness testimony and, 245–247
 forgetting and, 249–250
 of incomplete knowledge, 242
 recall and, 226, 238–239
 recognition and, 226
 of repressed memories, 250–253, 257
 retrieval cues and, 239, 240
 schemas and, 244–245
 from semantic memory, 240–243
 semantic networks and, 241–242
- Retrieval cues** *Stimuli that allow people to recall or recognize information stored in memory, 239, 240, 249*
- Retroactive interference** *A cause of forgetting in which new information placed in memory interferes with the ability to recall information already in memory, 248, 249*
- Retrograde amnesia** *A loss of memory for events prior to a brain injury, 256, 257*
- Reuptake process, 642
- Reversibility, 446
- Reversible figures, 155
- Rewards, aggression and, 697
- Ribonucleic acid (RNA), A-1
- Risperidone (Risperdal), 635, 638
- RNA, *see* Ribonucleic acid
- Rock music, subliminal messages in, 314–315
- Rods** *Highly light-sensitive, but color insensitive photoreceptors in the retina that allow vision even in dim light, 114, 115*
- Role theory** *A theory that hypnotized people act in accordance with a special social role that provides a socially acceptable reason to follow the hypnotist's suggestions, 328, 329*
- Romantic love, 675
- Rooting reflex, 438
- Rorschach Inkblot Test, 548, 549
- Rubella (German measles), 375, 436
- Rules of logic** *Sets of statements that provide a formula for drawing valid conclusions, 274–276*
- Ruminative style, depression and, 581
- Ruminative thinking, 493–494
- s** *A group of special abilities that Charles Spearman saw as accompanying general intelligence (g), 365*
- SAD, *see* Seasonal affective disorder
- Safety motives, 409, 410
- Saint-John's-wort (*Hypericum perforatum*), 636

 intimate relationships and, 673
 memory and, 229
 social identity and, 650–651
- Self-efficacy
 health behaviors and, 511
 perceived, 534–535
- Self-esteem** *The evaluations people make about how worthy they are as human beings, 543, 647, 648–650*
 achievement and, 404
 in adolescence, 468

- Self-fulfilling prophecy** *A process through which an initial impression of someone leads that person to behave in accordance with that impression, 654–655*
- Self-help books, positive reinforcement and, 208**
- Self-help groups, 629**
group therapy and, 620–621
- Self-perception theory** *A theory suggesting that attitudes can change as people consider their behavior in certain situations, then infer what their attitude must be, 664–665*
compliance and, 688
- Self-regulation** *The ability to control one's emotions and behavior, 464*
- Self-reports, personalities assessed with, 545**
- Self-schemas** *Mental representations that people form of themselves, 651–652*
- Self-serving bias** *The tendency to attribute one's successes to internal characteristics while blaming one's failures on external causes, 659*
- Self, social influences on, 647–652**
self-esteem and, 647, 649–650
self-schemas and, 651–652
social comparison and, 647–650
social identity theory and, 650–651
- Self theory, 538–540**
- Semantic encoding** *The mental representation of an experience by its general meaning, 226, 231, 236–237, 245*
- Semantic memory** *A type of memory containing generalized knowledge of the world, 226, 227, 240–244, 276, 476*
- Semantic memory networks, 241–242**
- Semantics** *Rules governing the meaning of words and sentences, 293*
- Semicircular canals** *Arc-shaped tubes in the inner ear containing fluid that, when shifted by head movements, stimulate nerve cells that provide information to the brain about the rate and direction of those movements, 137*
- Sensations** *Messages from the senses which comprise the raw information that affects many kinds of behavior and mental processes, 100*
- Sense** *A system that translates information from outside the nervous system into neural activity, 100*
- Sensitivity** *The ability to detect a stimulus, 149–150, 151–152*
- Sensitivity training, 540–541**
- Sensitization, 186–187**
- Sensorimotor period** *The first of Piaget's stages of cognitive development, when the infant's mental activity is confined to sensory perception and motor skills, 440, 441–442*
- Sensory cortex** *The parts of the cerebral cortex located in the parietal, occipital, and temporal lobes that receives stimulus information from the skin, eyes, and ears, respectively, 76–77, 102, 103*
- Sensory memory** *A type of memory that holds large amounts of incoming information very briefly, but long enough to connect one impression to the next, 231, 232–233, 239*
- Sensory receptors** *Specialized cells that detect certain forms of energy, 101*
- Sensory registers** *Memory systems that hold incoming information long enough for it to be processed further, 232–233*
- Sensory systems** *The parts of the nervous system that provide information about the environment, 63, 99–142*
in adulthood, 474
biology and, 103–104
brain and, 76–77

 Spines, 254
 Spleen, 95, 96
 Split-brain studies, 79–80
 Split-half method, 351
Spontaneous recovery *The reappearance of the conditioned response after extinction and without further pairings of the conditioned and unconditioned stimuli*, 189, 190
Sport psychologists *Psychologists who explore the relationships between athletic performance and such psychological variables as motivation and emotion*, 7
 motion perception and, 161–162
 Spread, *see* Variability, measures of
Spreading activation *A principle that explains how information is retrieved in semantic network theories of memory*, 241
 SRRS, *see* Social Readjustment Rating Scale
 SSRIs, *see* Selective serotonin reuptake inhibitors
Standard deviation (SD) *A measure of variability that is the average difference between each score and the mean of the data set*, 44, 46, A-11, A-12
 Standardized test, 350–351. *See also* IQ test
Standard scores *A value that indicates the distance, in standard deviations, between a given score and the mean of all the scores in a data set*, A-13
Stanford-Binet *A test for determining a person's intelligence quotient, or IQ*, 346, 347, 349
 Stapes, 106, 107, 110
State-dependent *Referring to memories that are aided or impeded by a person's internal state*, 240
State of consciousness *The characteristics of consciousness at any particular moment*, 311, 317–318. *See also* Hypnosis; Psychoactive drugs; Sleep; Meditation
State theory *A theory that hypnosis is an altered state of consciousness*, 328, 329
Statistically significant *In statistical analysis, a term used to describe the results of an experiment when the outcome of a statistical test indicates that the probability of those results occurring by chance is small (usually less than 5 percent)*, 46, 47, A-15
 Statistics, 30, A-10–A-18
 critical thinking and, 47
see also Data; Descriptive statistics; Inferential statistics
 STDs, *see* Sexually transmitted diseases
 Stem cells, Parkinson's disease and, 83
 Stepping reflex, 438
Stereotypes *False assumptions that all members of some group share the same characteristics. See* Prejudice/stereotypes
 Stereotype threat, 364
 Stevens's power law, 153
Stimulants *Psychoactive drugs that have the ability to increase behavioral and mental activity*, 330, 332, 335–337, 339, 386, 696

CHAPTER 1

Introducing Psychology

MULTIPLE-CHOICE QUESTIONS

Sample Quiz 1

1. Psychology is the study of
 - a. the development of cultures, religions, and societies.
 - b. behaviors and mental processes.
 - c. earth, nations, plant life, and animals.
 - d. how people relate to each other.
2. Introspection was a technique Wilhelm Wundt used in an attempt to
 - a. investigate consciousness as more than the sum of its parts.
 - b. uncover unconscious processes.
 - c. observe conscious experience.
 - d. study memory.
3. A psychologist who thinks current behavior is caused by unconscious conflicts was most likely trained in
 - a. behaviorism.
 - b. functionalism.
 - c. gestalt psychology.
 - d. psychoanalysis.
4. Which of the following is NOT a modern approach to psychology?
 - a. Behavioral
 - b. Cognitive
 - c. Evolutionary
 - d. Functionalism
5. Sometimes Janessa treats her clients with drugs, but at other times she tries to change the patterns of rewards and punishments the person receives. Janessa's approach can best be described as
 - a. behavioral.
 - b. biological.
 - c. eclectic.
 - d. humanistic.
6. To understand what rewards a child receives for bullying other children, we would most likely use
 - a. cognitive science.
 - b. functional analysis of behavior.
 - c. introspection.
 - d. psychoanalysis.

7. Dr. Atilano says that behavior is caused by activity in the nervous system, genetic inheritance, and hormones. Dr. Atilano takes a _____ approach to psychological phenomena.
- biological
 - psychodynamic
 - behavioral
 - cognitive
8. An instructor tells you that the evolutionary approach best characterizes her viewpoint. Which of the following statements is she most likely to agree with?
- Each person learns what behaviors are best.
 - Over generations, maladaptive behaviors will become less and less common in a species.
 - People do what makes them feel good.
 - We inherit only adaptive behaviors.
9. Deon believes that his friend Tom drives too fast on the interstate because Tom is unconsciously wishing for death. Deon suggests that Tom can't admit he feels guilty about being independent from his family. Deon most likely has a _____ approach to psychology.
- behavioral
 - biological
 - cognitive
 - psychodynamic
10. Mercedes often procrastinates when faced with a big assignment. A psychologist with a behavioral approach would be most likely to say that Mercedes procrastinates because she
- believes it helps her to get motivated later.
 - perceives the assignment as unfair and overwhelming.
 - is rewarded by the lighter workload during her early avoidance of the project.
 - unconsciously desires to fail her assignment.
11. Psychologists who emphasize the role of mental processes in explaining behavior take a(n) _____ approach.
- evolutionary
 - biological
 - cognitive
 - deterministic
12. Hassan believes his clients are basically good; therefore, he wants to see things from their point of view. Because Hassan also says that if he can understand a client's feelings and perceptions he will be better able to help them achieve their potential, Hassan is most likely a(n) _____ psychologist.
- developmental
 - evolutionary
 - humanistic
 - social
13. Francis majors in education and wants to understand the processes involved in learning and memory. Which of the following courses would best help Francis reach his goal?
- Cognitive psychology
 - Neuroscience
 - Clinical psychology
 - Social psychology
14. You are a biological psychologist interested in the emotional reactions of students to exams. Which of the following would be of most interest to you?
- Hormone levels
 - How much support the student has from peers
 - The dreams a student has before an exam
 - Attitudes toward learning

15. Maria watches people to discover what unwritten rules for behavior they are following. Maria sees that people tend not to sit next to another person on the bus unless empty seats are limited. Maria's interests are most like those of psychologists in the _____ subfield.
- clinical
 - developmental
 - personality
 - social
16. Michelle studies how sociable, conscientious, and anxious children are at age 8. She intends to see if she can predict differences in the number of years of school they have completed by age 25. Michelle is most likely a _____ psychologist.
- community
 - humanistic
 - personality
 - social
17. Which of the following is the best example of the work of a psychologist in the clinical subfield?
- Sadie observes how changes in playground equipment affect the interactions between children.
 - Tad attempts to assist people who are extremely depressed.
 - Val compares the IQ scores of sociable people with those of shy people.
 - Vince wonders if people's hormones influence their thinking.
18. Dr. Li tests students at a grade school and makes recommendations about who may benefit from an accelerated program and who may need a specific type of tutoring. Dr. Li is most likely a(n) _____ psychologist.
- community
 - industrial-organizational
 - personality
 - school
19. An industrial-organizational psychologist would be most interested in which of the following questions?
- How can we promote a stop-smoking campaign?
 - What type of management style would generate the highest productivity?
 - What mental steps are involved in perception and decision making?
 - How do social skills evolve from the preschool years through old age?
20. David doesn't get any laughs from the audience in response to his comedy monologue. If David is from a collectivist culture, he will be most likely to think.
- "It's my writers' fault I wasn't funny."
 - "I know I am funnier than other comedians: I just had a bad night."
 - "My sense of humor is too sophisticated for this crowd."
 - "It's my fault I wasn't funny enough for my audience."

Total Correct (See answer key) _____

Sample Quiz 2

Use this quiz to reassess your learning after taking Quiz 1 and reviewing the chapter.

- A psychologist may be concerned with which of the following questions:
 - Do the biochemical processes of people with schizophrenia differ from those of normal individuals?
 - Does urban crowding cause higher crime rates?
 - Does the decision-making process vary with the number of factors involved in the decision?
 - All of the above
- After speculating that a noisy environment reduces helping behavior, a psychologist using empiricism will most likely
 - describe to talk-show viewers how noise affects us.
 - design research to test the idea.

- c. try to reduce noise in the environment.
 - d. try to help someone in a noisy environment.
3. Ming's research involves presenting participants with objects and asking them to report the sensations that they are experiencing. Ming is most likely a
- a. functionalist.
 - b. structuralist.
 - c. behaviorist.
 - d. humanist.
4. Roberto studies what people enjoy about listening to classical music. Roberto claims that it would be useless to isolate and listen to only a rhythm, a violin part, or any other single aspect of music because it is the perception of the complete piece that is important. Roberto's emphasis on *not* dividing music into parts is most similar to
- a. structuralism.
 - b. behaviorism.
 - c. gestalt psychology.
 - d. psychoanalysis.
5. Larry says that people act the way they learned to act. Larry believes that if others stop rewarding a person's annoying behaviors, those behaviors will lessen. Larry most likely has a(n) _____ approach to psychology.
- a. behavioral
 - b. cognitive
 - c. evolutionary
 - d. humanistic
6. Paul's aunt thinks that Paul acts aggressively because he wants immediate gratification, so she insists that he learn to control his natural impulses. The approach most similar to her views is
- a. evolutionary.
 - b. psychodynamic.
 - c. biological.
 - d. functionalism.
7. A cognitive psychologist investigating why students study regularly would be most interested in
- a. the students' decisions about the advantages and disadvantages of putting off work.
 - b. the students' hidden internal conflicts.
 - c. how diet and exercise influence motivation level.
 - d. how past rewards and punishments have maintained this behavior.
8. Marissa says that she often doesn't attend classes because she doesn't find her courses interesting. Her roommate, Leslie, claims that Marissa doesn't attend because her natural drive toward self-improvement has been blocked. Leslie's view is most similar to a psychologist with a _____ approach.
- a. humanistic
 - b. psychodynamic
 - c. biological
 - d. cognitive
9. Helen, a first-year college student, wants to become a biological psychologist. Her counselor will probably tell her to take which of the following courses?
- a. Cognitive development
 - b. Physiology of behavior
 - c. The history of Freud
 - d. Community medical prevention programs
10. Lillia believes that to study consciousness you must study it as a total experience, not attempting to break it into parts. Lillia is most likely a(n)
- a. Gestalt psychologist.
 - b. structuralist.

- c. functionalist.
 - d. behaviorist.
11. Bill's therapist told him that his thought patterns cause his depression. Bill's therapist follows the _____ approach to psychological phenomena.
- a. biological
 - b. psychodynamic
 - c. cognitive
 - d. behavioral
12. Brendan runs a diversity training program that allows people to discuss stereotypes and become more accepting of people with different backgrounds. Brendan is especially interested in the effect his training has on the ability of employees to work together. Brendan is most likely a(n) _____ psychologist.
- a. cognitive
 - b. community
 - c. industrial-organizational
 - d. personality
13. Rajesh is very concerned about meeting his parents' expectations. Rajesh doesn't want to attract attention to himself; therefore, when he is successful, he will usually emphasize the role his family played in helping him to achieve. Rajesh's behavior indicates he may be from a(n) _____ culture.
- a. collectivist
 - b. communist
 - c. democratic
 - d. individualist
14. Alisha notices people in her classes becoming friends and wonders what attracts people to each other. Alisha's interests are most like those of psychologists in the _____ subfield.
- a. clinical
 - b. developmental
 - c. personality
 - d. social
15. Jill wants to start a personal-service business offering nannies, an adolescent big-brother and big-sister program, and companions for the elderly. Jill must be able to teach her employees how to fulfill the psychological needs of every age group. Jill should study _____ psychology.
- a. biological
 - b. psychodynamic
 - c. developmental
 - d. cognitive
16. On a bus you overhear a man talking to himself. The man appears to be getting angry and eventually starts pounding one fist into the other palm and shouting unintelligibly. Because he seems like he has a psychological disorder and may need help, you would want to recommend that someone call a _____ psychologist.
- a. clinical
 - b. developmental
 - c. personality
 - d. social
17. A psychologist who wants to prevent disorders by ensuring children have proper nutrition and educational opportunities is most likely a(n) _____ psychologist.
- a. biological
 - b. clinical
 - c. community
 - d. educational

18. Candace is interested in helping athletes learn visualization skills that will help them better perform in competition. Candace's interests are most like those of a psychologist in which subfield?
- a. biological
 - b. clinical
 - c. cognitive
 - d. Sport
19. Kwasi wants to know which study techniques are most efficient for which types of tests; therefore, he should consult a(n) _____ psychologist.
- a. behavioral
 - b. clinical
 - c. educational
 - d. school
20. Cultures in which personal goals are more important than group goals are termed
- a. multicultural.
 - b. individualist.
 - c. collectivist.
 - d. subcultural.

Total Correct (See answer key) _____

ANSWERS TO MULTIPLE-CHOICE QUESTIONS

Circle the question numbers you answered correctly.

Sample Quiz 1

1. *b* is the answer. Psychologists research the actions and thoughts of organisms. Psychologists also try to help people who have difficulty coping. (see *The World of Psychology*)
 - a.* An anthropologist would probably study the development of societies.
 - c.* The focus of psychology is narrower: geography is the study of the earth and its many inhabitants.
 - d.* Psychology is much more than the study of human interaction: psychologists may study development, learning, memory, psychological disorders, and much more.
2. *c* is the answer. Wundt used introspection to try to break down consciousness into separate observable elements. (see *A Brief History of Psychology*)
 - a.* Gestalt psychologists argued that consciousness is more than the sum of its separate elements.
 - b.* Sigmund Freud theorized that the basis of all human behavior was the unconscious.
 - d.* Hermann Ebbinghaus developed techniques and early experiments to study memory.
3. *d* is the answer. Psychoanalysis is a treatment strategy that assumes that people are influenced by conflicts of which they are unaware. (see *A Brief History of Psychology*)
 - a.* Behaviorists emphasize that people learn from the consequences of their behavior. The behavioral approach does not recognize the unconscious as an influence on people's behavior.
 - b.* Functionalism wanted to understand how consciousness works but did not study the unconscious.
 - c.* Gestalt psychology viewed consciousness as an experience that could not be divided into its parts: Gestalt psychologists did not concern themselves with the unconscious.
4. *d* is the answer. James's functionalism influenced modern psychologists to study memory, education, and intelligence, but it is not a modern approach. (see *A Brief History of Psychology*)
 - a, b, c.* Current psychologists may use the behavioral, cognitive, or evolutionary approach, among others.
5. *c* is the answer. Many psychologists choose what they consider to be the best features of several approaches and use whatever feature or combination of features will be most helpful to a client. (see *Approaches to Psychology*)
 - a.* A person with a behavioral approach would try to change the pattern of rewards and punishments but would not use drug therapy.

- b.* The biological approach would view drug treatment as a reasonable way to alter the chemical or hormonal imbalances that caused the problematic behavior, but it would not agree with altering the reward and punishment patterns.
- d.* A humanistic psychologist would be interested in a person's unique perceptions; therefore, a humanistic psychologist would not prescribe drugs or change the consequences of a client's behavior.
6. *b* is the answer. A behaviorist using functional analysis of behavior would study the events following a child's actions to see what benefits the actions have. (see A Brief History of Psychology)
- a.* Cognitive science is a multidisciplinary approach to the study of thought and mental abilities, not a method for analyzing a behavior's consequences.
- c.* Introspection is a method used by structuralists to investigate consciousness.
- d.* Psychoanalysis was begun by Freud as a means of uncovering unconscious struggles, not as a means of discovering the impact of overt behaviors.
7. *a* is the answer. Biological psychologists assume that nervous-system activity, hormones, and genetic inheritance cause behavior. (see Approaches to Psychology)
- b.* The psychodynamic approach assumes that behavior results from our struggle to fulfill instinctive desires despite society's restrictions.
- c.* The behavioral approach assumes that behavior is caused by people's past experiences of rewards and punishments.
- d.* The cognitive approach assumes that behavior is caused by the thoughts involved with that behavior.
8. *b* is the answer. The evolutionary approach looks for evidence that organisms improve over generations. Those behaviors that were not helpful would be replaced by behaviors that were. (see Approaches to Psychology)
- a.* The behavioral approach would agree that people learn what is adaptive for them, but the evolutionary approach would go on to say that organisms that cannot adjust to their environment do not survive.
- c.* A Freudian might take the view that people do what feels good, especially if a person has not learned about the limits society places on behavior.
- d.* We do not inherit **only** adaptive behaviors.
9. *d* is the answer. The psychodynamic approach describes behavior as guilt-driven or unconsciously influenced. (see Approaches to Psychology)
- a.* The behavioral approach does not address unconscious motives.
- b.* To psychologists with the biological approach, the cause of behavior is physiological rather than intellectual.
- c.* The cognitive approach emphasizes conscious thoughts, memories, and decisions.
10. *c* is the answer. A psychologist with the behavioral approach would look to the consequences of procrastination for an explanation of why Mercedes waits to do an assignment. (see Approaches to Psychology)
- a.* Motivation is a cognitive factor not dealt with by the behavioral approach.
- b.* Beliefs and feelings are cognitive factors that would be addressed by the humanistic approach.
- d.* The unconscious is part of the psychodynamic approach.
11. *c* is the answer. Cognitive psychologists investigate thoughts and information-processing. (see Approaches to Psychology)
- a.* The evolutionary approach is in agreement with Darwin's theory that adaptive behaviors will survive in a species, but it does not study current mental processes.
- b.* Mental processes are influenced by physiology, according to biological psychologists; therefore, physiology would be emphasized by biological psychologists.

- d.* The deterministic approach is not one of the major approaches to psychology.
12. *c* is the answer. Humanistic psychologists are concerned with viewing things from their clients' perspective. (see Approaches to Psychology)
- a.* Developmental psychologists study people across the life span.
- b.* Psychologists with an evolutionary approach do not try to help clients improve. They believe that we inherit adaptive characteristics; therefore, they do not focus on a person's perceptions.
- d.* Social psychologists research how people interact.
13. *a* is the answer. Cognitive psychologists study the processes of learning and memory. (see Subfields of Psychology)
- b.* Neuroscience research may include studies on the neurological changes accompanying learning. However, Francis would have difficulty directly applying such knowledge to the teaching of his students.
- c.* Although clinical psychologists may have patients whose learning problems result from disorders, they do not focus their research in this area.
- d.* Social psychologists study interactions between people. This information will help Francis understand students' social behaviors but not the processes of learning and memory.
14. *a* is the answer. Psychologists who take a biological approach would emphasize the relationship between emotions and physiological factors such as nervous system and hormonal activity. (see Approaches to Psychology)
- b.* Support from peers would be a concern of social psychologists.
- c.* Dreams might be analyzed by a psychodynamic psychologist.
- d.* Attitudes toward learning would interest cognitive psychologists.
15. *d* is the answer. Social psychologists are interested in how people influence each other's behavior. (see Subfields of Psychology)
- a.* Clinical psychologists study disorders and find ways to assist people in coping with disorders.
- b.* A developmental psychologist researches the changes that take place in people as they age.
- c.* Personality psychology documents individual differences but does not study how people are affected by others.
16. *c* is the answer. A personality psychologist conducts research on long-lasting differences between people, much like Michelle's study of the association between a personality description and later behavior. (see Subfields of Psychology)
- a.* Community psychologists work to prevent psychological disorders.
- b.* A person with a humanistic approach would focus on immediate experience and current perceptions instead of looking for a relationship between early judgments and later behavior.
- d.* Social psychologists look for general rules about how people interact.
17. *b* is the answer. Clinical psychologists help people cope with stressors and psychological disorders. (see Subfields of Psychology)
- a.* Sadie is a social psychologist.
- c.* Val is a personality psychologist.
- d.* Vince is a biological psychologist.
18. *d* is the answer. School psychologists watch for learning disabilities and giftedness in order to arrange for special education if warranted. (see Subfields of Psychology)
- a.* Community psychologists might be interested in keeping problems in academic achievement from occurring, but they would not be trained in educational testing and program placement.
- b.* Industrial-organizational psychology is the study of social behavior in the workplace.

- c.* Personality psychologists might research the influence of personality characteristics on student achievement, but they do not specialize in educational testing and placement as school psychologists do.
19. *b* is the answer. Industrial-organizational psychologists study social behavior, such as a supervisor's style of communication at work. (see Subfields of Psychology)
- a.* Health psychologists study promoting healthy lifestyles.
- c.* Cognitive psychologists study perception, learning, memory, judgment, and decision making.
- d.* Developmental psychologists research how and why behavior and mental processes change over the life span.
20. *d* is the answer. If David is from a collectivist culture, he is likely to give others credit when he succeeds but to blame himself when he fails. (see Human Diversity and Psychology)
- a. c.* A person from a collectivist culture would be unlikely to blame others for a failure.
- b.* People in collectivist cultures are unlikely to emphasize their unique qualities.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 1 that you answered correctly.

ANSWERS TO MULTIPLE-CHOICE QUESTIONS

Circle the question numbers you answered correctly.

Sample Quiz 2

- d* is the answer. Psychologists are concerned with all behaviors and mental processes. Aberrant biochemical processes are a possible cause of schizophrenic behavior. Crime is a behavior, and decision making is a mental process. (see The World of Psychology)
- b* is the answer. After speculating that a noisy environment reduces helping behavior, Mathews and Canon designed research that indicated that stimulus overload makes people less likely to help. (see Research: The Foundation of Psychology)
 - Before empiricists describe a phenomenon, they study it.
 - Trying to reduce noise in the environment before we know if it is the true cause of reduced helping behavior might be a waste of effort; therefore, empiricists see if their hunches are correct.
 - Helping someone in a noisy environment, while it is a nice thing to do, does not show whether noise influences most people's helping behavior.
- b* is the answer. Structuralists used the method of introspection to determine the elements of or the structure of consciousness. (see A Brief History of Psychology)
 - Functionalists studied consciousness, but they used a more experimental approach rather than introspection.
 - Behaviorists study behavior, not consciousness.
 - Humanists are interested in people's natural tendency toward growth, not in identifying elements of sensation.
- c* is the answer. Gestalt psychologists criticized other approaches for splitting up experience into its components rather than studying consciousness as a whole experience. (see A Brief History of Psychology)
 - Structuralism tried to identify the elements of sensation through introspection. People using introspection would often divide their experience into parts such as quality, intensity, and clarity.
 - A behaviorist studies behaviors and the rewards and punishments that follow.
 - Psychoanalysis is a method for identifying hidden conflicts and memories that affect current behavior.

5. *a* is the answer. The behavioral approach emphasizes that people think and behave in ways that have been previously rewarded. (see Approaches to Psychology)
 - b*. The cognitive approach emphasizes what people *think* about a situation and the consequences of their behavior and emphasizes the way people process incoming information.
 - c*. Evolutionists try to understand the environmental conditions that encourage (reward) behaviors; however, rather than trying to change the consequences, they emphasize that adaptive behaviors are passed on to future generations.
 - d*. The humanistic approach emphasizes the role of a person's view of the situation.
6. *b* is the answer. Psychodynamic theory suggests that there is a tension between natural impulses and society's rules. (see Approaches to Psychology)
 - a*. The evolutionary approach explains current behaviors as the result of natural selection.
 - c*. A person with a biological approach would look to the influence of drugs, chemical imbalances, and other physiological characteristics as the cause of current behaviors.
 - d*. Functionalism did not comment on impulses or societal control; instead, it documented how mental events were adaptive.
7. *a* is the answer. Cognitive psychologists are interested in conscious decision making. (see Approaches to Psychology)
 - b*. Internal conflicts are in the realm of psychodynamic psychologists.
 - c*. Diet and exercise would most likely interest a biological psychologist.
 - d*. Behavioral psychologists want to know what rewards and punishments maintain a behavior.
8. *a* is the answer. The humanistic approach stresses that people are basically good and will work toward improving themselves unless stopped by something major. (see Approaches to Psychology)
 - b*. The psychodynamic approach downplays the role of positive impulses and plays up the role of unconscious conflicts and negative impulses.
 - c*. Biological psychology emphasizes the importance of body chemistry in everyday life.
 - d*. Cognitive psychology does not recognize a drive toward self-improvement.
9. *b* is the answer. Helen will learn which physiological processes affect behavior. (see Subfields of Psychology)
 - a*. Cognitive development is the study of the development of thinking.
 - c*. Clinical, personality, and developmental psychologists may be interested in discussing and testing Freud's ideas, but biological psychologists probably would not.
 - d*. Community psychologists develop and operate prevention programs.
10. *a* is the answer. Gestalt psychologists believe that the whole is greater than the sum of the parts; consequently, they believe consciousness should be studied as a whole experience. (see A Brief History of Psychology)
 - b*. Structuralists prefer to study the components of consciousness.
 - c*. Functionalists believe one should study the function, or purpose, of consciousness.
 - d*. Behaviorists believe that one should not study unobservable phenomena such as consciousness.
11. *c* is the answer. The cognitive approach assumes that behavior results from the thoughts involved in that behavior. (see Approaches to Psychology)
 - a*. The biological approach assumes that genetic inheritance, nervous-system activity, and hormones cause behaviors.
 - b*. The psychodynamic approach assumes that behavior is a result of our struggle to fulfill instinctive desires despite society's restrictions.
 - d*. The behavioral approach assumes that behavior is caused by the rewards and punishments experienced by individuals in response to their behaviors.

12. *c* is the answer. Industrial-organizational psychologists research the influence of employee interactions and management structures on employee productivity. (see Subfields of Psychology)
- a.* Cognitive psychologists might study mental processes involved in prejudice; however, they would be unlikely to study the impact of diversity training on employee relations.
 - b.* Community psychology attempts to reach people in need by providing affordable mental health care in the community.
 - d.* Personality psychologists study how people differ from each other, but do not study employee interactions.
13. *a* is the answer. People in collectivist cultures tend to try not to attract attention to themselves and are likely to credit their family or work group if they are successful. (see Human Diversity and Psychology)
- b.* A communist society may or may not be collectivist.
 - c.* A democratic society may or may not be collectivist.
 - d.* Individualist cultures emphasize individuality. If Rajesh were from an individualist culture, he would be likely to take credit for his success.
14. *d* is the answer. Interpersonal attraction is a topic of interest to social psychologists. (see Subfields of Psychology)
- a.* Clinical psychology deals with psychological disorders.
 - b.* A developmental psychologist would study differences in people as they age.
 - c.* Personality psychology looks for similarities within an individual over time but does not study interpersonal attraction.
15. *c* is the answer. Developmental psychologists are interested in understanding how and why behavior and mental processes change over the life span. (see Subfields of Psychology)
- a.* Biological psychology would teach Jill the areas of the brain and the physiological processes that are involved in learning, but this knowledge would be difficult for her personnel to apply in their jobs.
 - b.* Psychodynamic psychology would teach Jill that behavior is determined by the combination of unconscious internal conflicts and external (parents', peers', or society's) reactions to those conflicts. However, this approach would not help Jill fulfill changing needs for different age groups.
 - d.* Cognitive psychology would help Jill understand certain useful principles of learning. However, she must understand how learning and many other behaviors and mental processes change over the life span in order to help people of all ages.
16. *a* is the answer. A clinical psychologist would be most qualified to work with a person who has a psychological disorder. (see Subfields of Psychology)
- b.* Developmental psychologists study age differences and do not provide counseling.
 - c.* A personality psychologist might be interested in the person's unique personality but would not be able to offer counseling.
 - d.* Social psychology is the study of how people influence one another; however, it does not study disorders or treatment.
17. *c* is the answer. Community psychology not only provides counseling service in the community but also works to reduce the number of risks that contribute to the appearance of disorders. (see Subfields of Psychology)
- a.* Biological psychology investigates the influence of physiological factors on behavior but does not seek to prevent disorders.
 - b.* Clinical psychologists are trained to help people once they have a disorder.
 - d.* Educational psychology focuses on learning and teaching strategies but would not address the prevention of disorders through nutrition.

18. *d* is the answer. Sport psychologists explore the relations between performance and psychological variables. (see Subfields of Psychology)
- a.* Biological psychologists are more interested in the nervous system, immune system, and hormonal balance than in test evaluation.
 - b.* A person in clinical psychology researches disorders and designs treatments.
 - c.* Cognitive psychology focuses on thought processes.
19. *c* is the answer. Educational psychologists research studying and teaching techniques. (see Subfields of Psychology)
- a.* A psychologist with a behavioral approach would know about incentives but could not advise Kwasi on specific study techniques.
 - b.* Clinical psychologists are concerned with psychological disorders, not study habits.
 - d.* School psychologists administer IQ tests, identify learning problems, and set up educational programs to assist students; however, they do not research general study strategies.
20. *b* is the answer. Individualist cultures emphasize and reward behavior that contributes to the success of the individual person even if it sometimes occurs at the group's expense. (see Human Diversity and Psychology)
- a.* Multicultural refers to the existence of more than one culture within a given geographic boundary such as a country (Kenya) or a city (Los Angeles).
 - c.* Collectivist cultures emphasize and reward behaviors that contribute to the success of the group. Remember, collectivist cultures emphasize "collections" of people (groups) over the individual.
 - d.* Subcultures are part of a multicultural society.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 2 that you answered correctly.

For each question you answered correctly, circle its number. (Quiz 1 numbers are not shaded; Quiz 2 numbers are shaded.) Are there patterns in the types of questions or the topics you got wrong that could direct your further study? Did you improve from Quiz 1 to Quiz 2?

CHAPTER 2

Research in Psychology

MULTIPLE-CHOICE QUESTIONS

SAMPLE QUIZ 1

1. Sue, having had no experience with the breed, has purchased what a breeder claims are two purebred Abyssinian cats: Chessie and Baby. She hypothesizes that Baby is not really pure in breed because she doesn't act like Chessie. According to the critical thinking steps in your text, what does Sue need to do?
 - a. Restate her hypothesis.
 - b. Reexamine the behavioral differences between her two cats.
 - c. Compare the behavior of other Abyssinians to her cats' behavior.
 - d. Conclude that one of her cats is not purebred.

2. Researchers are investigating the effects of caffeine on test performance. They divide a randomly selected sample of students into three groups. One group drinks a cup of caffeinated water. *Water Joe*; another group drinks a cup of spring water; and a third group drinks nothing. All take a vocabulary test. What is the operational definition of the independent variable in this study?
 - a. Caffeine
 - b. *Water Joe*
 - c. Spring water
 - d. Vocabulary test
3. Methods for collecting descriptive data include all of the following *except*
 - a. naturalistic observations.
 - b. experiments.
 - c. case studies.
 - d. surveys.
4. Dr. McMarty has collected data by doing case studies and naturalistic observation on a new phenomenon never studied before. Her next step will probably be to
 - a. design an experiment.
 - b. examine the data for patterns and make predictions.
 - c. check for statistical significance.
 - d. form an explanation that will lead to a theory.
5. Which should be studied by naturalistic observation?
 - a. The self-esteem of teenage mothers
 - b. Whether a new therapy works better with individuals or groups
 - c. How often three-month-old infants wake up during the night
 - d. The attitudes on cloning among people in Terre Haute, Indiana
6. Case studies are used to
 - a. avoid a placebo effect.
 - b. determine the effects of an independent variable on a dependent variable.
 - c. collect descriptive data.
 - d. provide control in an experiment.
7. In an experiment the _____ variable is manipulated and the _____ variable is measured.
 - a. dependent, independent
 - b. confounding, dependent
 - c. independent, confounding
 - d. independent, dependent
8. Before using survey results to support a hypothesis, one must be sure that
 - a. the questions are properly worded.
 - b. the sample used is representative of the population being studied.
 - c. the responses are not biased by "socially acceptable" standards.
 - d. all of the above.
9. The experimental design that prevents experimenter bias from confounding a study's results is
 - a. operational definition.
 - b. naturalistic observation.
 - c. random.
 - d. double-blind.

10. Akuba believes that group activities will result in better learning than lectures. She gives one of her introductory psychology classes lectures and the other class group activities. She then compares how they perform on exams. In this example, which class received lectures versus group activities is the _____ variable.
- confounding
 - dependent
 - independent
 - placebo
11. Jeremy designed an experiment to test the effects of praise on the sharing behavior of children. Children in Group A will be praised after they share; children in Group B will only be observed. Group A is the _____ group.
- control
 - experimental
 - operational
 - random
12. Part of the data comparing the number of sharing behaviors for the two groups are listed here. Group A: 35, 12, 11, 9, 8, 6, 5. Group B: 9, 8, 7, 7, 6, 5, 4. Which of the following statistics would best represent the amount of sharing for the children in Group A?
- Mean
 - Median
 - Mode
 - Range
13. Based on the data in question 12, which of the following statements about variability is most likely correct?
- Group A has a smaller range than Group B.
 - Group A does not have a standard deviation.
 - Group B has a smaller standard deviation than Group A.
 - Group B has the same range as Group A.
14. Detective Brown observed that when he and his coworkers drank caffeinated tea while working on cases, they solved them faster. Brown conducted an experiment in which one group received caffeine pills and the other received inert sugar pills. Each person received a set of cases to solve and Brown recorded the number of cases solved by people in the caffeine group versus people in the sugar pill group. The strongest evidence that caffeine pills improved the case solution rate would be
- a large mean for the caffeine group.
 - a positive correlation between the number of cases solved by the caffeine and the sugar pill groups.
 - a small range of scores in the sugar pill group.
 - statistically different means for the caffeine and sugar pill groups.
15. Susan wants to study the effects of peer pressure on study habits in first-year students at her university. She needs to obtain a random sample. How should she choose the subjects for her experiment?
- Select one dormitory and ask all of the first-year students residing there to participate in the experiment.
 - Randomly select names from the introductory psychology course roster.
 - Randomly select names from the dormitory phone book.
 - Randomly select names from a list of all first-year students at the university.
16. Choose the strongest correlation coefficient.
- + .75
 - .99
 - + .01
 - .01
17. A measure of central tendency
- is the average distance of scores from the mean of a data set.
 - describes the typical score in a data set.

- c. is the lowest score in a data set subtracted from the highest score.
 - d. determines if a sample is random or biased.
18. Several states implemented laws requiring drivers and passengers to wear seat belts. Since the laws' implementation, the number of accident-related deaths has decreased. Therefore, a negative correlation exists, which indicates that
- a. wearing seat belts causes fewer car accidents.
 - b. more laws result in fewer accident-related deaths.
 - c. when the number of people wearing seat belts increases, the number of accident-related deaths decreases.
 - d. enforcing the law causes fewer accidents to occur.
19. Because experimenters follow the ethical guidelines for psychologists, participants in psychological research can expect to be
- a. informed about the study before they agree to participate.
 - b. offered counseling.
 - c. psychoanalyzed.
 - d. sent home without knowing they were deceived.
20. The question that puzzles Marianne is why some psychological problems seem to run in families. Marianne would like to discover whether it is nature or nurture that more strongly influences certain behaviors; therefore, she has an interest in
- a. behavior genetics.
 - b. genetic engineering.
 - c. "pop" psychology.
 - d. replicability.

Total Correct (See answer key) _____

SAMPLE QUIZ 2

Use this quiz to reassess your learning after taking Quiz 1 and reviewing the chapter.

1. On a television program many people give testimony that they have never felt better than they have since they began using the Run-O-Sizer treadmill. Each person who is interviewed shows "before" and "after" photos depicting incredible weight loss and increased muscle tone. According to the critical thinking steps in your text, what should you do?
- a. Look for alternative ways of interpreting the evidence that the Run-O-Sizer works.
 - b. Draw your conclusion about the worth of the Run-O-Sizer based on the strong testimonials.
 - c. Decide whether to order the treadmill based on the price.
 - d. Order only if they offer a money-back guarantee.
2. The four scientific goals associated with research are
- a. measurement, prediction, control, and explanation.
 - b. explanation, understanding, reasoning, and control.
 - c. description, critical thinking, control, and explanation.
 - d. description, prediction, control, and explanation.
3. To document how the average first-year college student behaves during an exam, a researcher should conduct a(n)
- a. case study.
 - b. experiment.
 - c. naturalistic observation.
 - d. survey.

4. The Food and Drug Administration (FDA) has tested fluoxetine, a new drug thought to decrease depression without causing weight gain. The experiment consisted of a random sample of depressed patients split into two groups. The experimental group received the drug; the control group received no treatment. The results were clear: those patients receiving fluoxetine experienced a decrease in depression without weight gain; those in the control group reported no change in depression or weight. Based on these results, should the FDA allow marketing of fluoxetine?
 - a. No, the results may have been due to the placebo effect.
 - b. No, the study should be repeated using a case study.
 - c. Yes, the experimental design is appropriate and the results are clear.
 - d. No, the results may have been due to incorrect sampling.
5. In the experiment done by the FDA on fluoxetine, which variable needs an operational definition?
 - a. The independent variable
 - b. Fluoxetine
 - c. Depression
 - d. The placebo
6. In the experiment done by the FDA on fluoxetine, the drug was the
 - a. independent variable.
 - b. dependent variable.
 - c. operational measure.
 - d. random variable.
7. A psychologist interested in maximizing control of variables in her research would use which of the following methods?
 - a. Naturalistic observation
 - b. Surveys
 - c. An experiment
 - d. A case study
8. Questionnaires or special interviews designed to obtain descriptions of people's attitudes, beliefs, opinions, and behavioral intentions are known as
 - a. experiments.
 - b. surveys.
 - c. case studies.
 - d. naturalistic observations.
9. Which of the following hypotheses should be tested with a case study?
 - a. Thinking of examples of concepts while studying improves students' performance on tests.
 - b. An unpleasant odor presented for one hour will cause a mild negative emotional reaction.
 - c. Childhood abuse is associated with multiple personality disorder.
 - d. All of the above.
10. To discover what variables (such as how much control a subject has or how they perceive an event) may *cause* a person to react to a negative event with intense emotion, a researcher should use what research design?
 - a. Case study
 - b. Experiment
 - c. Naturalistic observation
 - d. Survey
11. Which of the following is a possible random variable?
 - a. Level of intelligence
 - b. State of health
 - c. Prior experience with the independent variable
 - d. All of the above

12. Nicole was struck by lightning, and she now often runs down the street singing while wearing her underwear on the outside of her clothes. She cannot concentrate on her work for more than 10 minutes, nor can she understand the comics she used to enjoy so much. To understand Nicole's condition, a researcher should use a(n)
 - a. case study.
 - b. experiment.
 - c. naturalistic observation.
 - d. survey.
13. Drawing a purely random sample from which of the following populations would be feasible?
 - a. The human race
 - b. New York City rats
 - c. U.S. presidents past and present
 - d. None of the above
14. Statistical analyses provide a means to
 - a. summarize and analyze research data.
 - b. measure the dependent variable.
 - c. measure the independent variable.
 - d. examine correlations for cause-effect relationships.
15. Following is a data set: 10, 11, 12, 22, 12, 11, 10, 10, 10, 11, 13. The value of 10 is the
 - a. mean.
 - b. mode.
 - c. median.
 - d. range.
16. A positive correlation indicates the existence of a relationship between two variables such that
 - a. one variable increases as the other decreases.
 - b. one variable increases as the other increases.
 - c. one variable causes an increase in the other.
 - d. one variable causes a decrease in the other.
17. A recruiter has administered an intelligence test to a college graduating class. The test results are rather disappointing, however. The means, medians, and modes of all the classes are very similar and very low. The recruiter is determined to find the class with the brightest students to interview. What statistic could this recruiter look at to decide which one of the classes probably has the greatest number of high scores?
 - a. The range
 - b. The standard deviation
 - c. A measure of central tendency
 - d. An operational score definition
18. You are studying the effects of alcohol consumption on decision-making time. Your hypothesis states that as alcohol consumption increases, decision-making time will also increase. If your data describe a _____ correlation, your hypothesis will be supported.
 - a. negative
 - b. curvilinear
 - c. positive
 - d. statistically significant negative
19. Why do psychologists follow ethical guidelines?
 - a. Psychologists would not want the cost of participating in an experiment to be too high in comparison to the information to be gained.
 - b. The American Psychological Association has set standards for psychologists to follow when conducting research and treating patients.
 - c. Stress and pain could act as confounding variables in an experiment.
 - d. All of the above

20. A psychologist is planning to examine the contributions of heredity and environment to intelligence. Of the methods listed below, the psychologist is most likely to use a(n)
- a. adoption study.
 - b. experiment.
 - c. factor analysis.
 - d. naturalistic observation.

Total Correct (See answer key) _____

ANSWERS TO MULTIPLE-CHOICE QUESTIONS

Circle the question numbers you answered correctly.

Sample Quiz 1

1. *c* is the answer. Because Sue has had no experience with the Abyssinian breed, she cannot assume that Baby isn't purebred because she doesn't act like Chessie. Baby's behavior may be *more* typical of Abyssinians. Sue must compare her cats' behavior with that of other Abyssinians before she can draw conclusions about the purity of *either* cat's breeding. (see Thinking Critically About Psychology)
 - a.* It is Sue's hypothesis that, if Baby doesn't act like Chessie, she may not be a pure Abyssinian. She needs to investigate alternative ways of interpreting her evidence, not change her hypothesis.
 - b.* Even if Sue checks the behavior of her cats again, she still needs to compare her cats with other Abyssinians before she can draw any conclusions.
 - d.* Before a conclusion is drawn, the evidence must support the hypothesis. Sue's evidence, the behavior of her two cats, is insufficient to draw a conclusion regarding their breeding.
2. *b* is the answer. *Water Joe*, the caffeinated water, is the exact, concrete way the independent variable of caffeine is defined and manipulated in this study. (see Critical Thinking and Scientific Research)
 - a.* Caffeine is the independent variable. Its operational definition is specifically being manipulated, in this case, as one cup of *Water Joe*.
 - c.* Spring water is the placebo; it has no caffeine.
 - d.* The vocabulary test is the dependent variable. It is what is being measured in this study.

3. *b* is the answer. In experiments, variables are not described; they are controlled to establish unambiguous cause-effect relationships. (see Experiments: Establishing Cause and Effect)
a, c, d. Naturalistic observations, case studies, and surveys are all methods used to describe and predict behavior and mental processes.
4. *b* is the answer. Dr. McMarty should examine the data for patterns between variables and make predictions to form hypotheses, the second goal in research. (see Research Methods in Psychology)
a. To design an experiment, one must have a hypothesis to test. Hypotheses are usually based on descriptive data; Dr. McMarty must examine the data before forming a hypothesis.
c. Statistics are used to test the significance of correlational and experimental data. Dr. McMarty must examine the data to find patterns or relationships between variables to form a hypothesis. After she tests the hypothesis, she can check for statistical significance.
d. Explanations are based on descriptive and experimental data. Dr. McMarty has only descriptive data. She should form a hypothesis based on relationships between variables in the data set and complete an experiment; then she may have information that will contribute to a theory.
5. *c* is the answer. The best way to obtain a true count of how many times an infant awakens is to observe the child in its natural surroundings. Parents may or may not furnish reliable information. (see Naturalistic Observation: Watching Behavior)
a. Which behaviors specifically indicate self-esteem? This is a debatable question. To avoid this problem, the best method is to interview the teenagers or to administer questionnaires designed to measure self-esteem.
b. Naturalistic observation will only provide opinions about whether individuals or groups have improved. To determine whether the therapy works better with groups or individuals, researchers sometimes conduct a quasi-experiment, varying the treatment in naturally occurring groups and individuals in therapy.
d. How do we observe an attitude? The most efficient way to find out how someone feels is to ask them. Therefore, a survey would be the best method.
6. *c* is the answer. (see Case Studies: Taking a Closer Look)
a. The placebo effect usually occurs in an experimental setting where subjects respond to a treatment that has no active ingredients.
b. Independent and dependent variables are used in experiments.
d. Case studies do not provide control; experiments do.
7. *d* is the answer. (see The Experimental Method)
a. The independent variable is manipulated; the dependent variable is measured.
b, c. A confounding variable is any aspect of the experiment that affects the dependent variable instead of or along with the independent variable. Researchers try to avoid the presence of confounding variables.
8. *d* is the answer. A subject may misinterpret an improperly worded question, thus biasing the data. Representative samples are important regardless of the research method used. A sample unrepresentative of the population of interest will diminish the usefulness of data in the formation of a theory regarding that population's behavior. And if the question is embarrassing, the subject may lie, thus again biasing the data. (see Surveys: Looking at the Big Picture)
9. *d* is the answer. In a double-blind experimental design, neither the subjects nor the experimenters know who has received the independent variable. The *experimenters cannot bias* the data in favor of their hypothesis, because they do not know which subjects received the independent variable. (see Experimenter Bias)
a. An operational definition is a statement of how a variable (for example, anxiety) is to be measured.
b. Naturalistic observation is a research method but not an experimental design.

- c. Random refers to the means by which the subjects were selected for a study. It is not an experimental method.
10. c is the answer. Akuba manipulated, or determined, which class would receive which treatment. Therefore, receiving group activities versus lecture is the independent variable. (see The Experimental Method)
- a. A confounding variable would be a variable that could effect the dependent variable along with the independent variable.
- b. The dependent variable in this study would be the test scores, because these were measured rather than manipulated.
- d. A placebo is a treatment that contains no active effect but may produce an effect on the dependent variable through participant expectation.
11. b is the answer. The experimental group receives the independent variable. (see The Experimental Method)
- a. The control group receives a placebo or no treatment.
- c, d. Operational groups and random groups are not part of experimental design; they do not exist.
12. b is the answer. The median is the middle score of a distribution and is a better description of a sample than the mean when the sample includes extreme scores. (see Measures of Central Tendency)
- a. The mean would be affected by the extreme score to give the impression that there was typically more sharing than there truly was. (With the high score of 35, the Group A mean is about 12.3; without it the Group A mean would be 8.5, which is closer to most of the numbers.)
- c. There is no mode in Group A since no scores were repeated.
- d. The range is not a measure of central tendency; it would only tell the distance between the highest and lowest scores.
13. c is the answer. Group B scores are very close to one another; therefore, the standard deviation for Group B should be smaller than for Group A, which has an extreme score. (see Measures of Variability)
- a. The range for Group A would be 30; the range for Group B would be 5. Therefore, Group A's range is larger.
- b. A standard deviation could be calculated for Group A.
- d. Groups A and B do not have the same range.
14. d is the answer. Statistically different means would show that the differences were unlikely to occur due to chance; this would be an indication that the experiment had an effect. (see Inferential Statistics)
- a. A large mean for the caffeine group would be a small amount of evidence for the hypothesis; however, the sugar pill group could also have a large mean.
- b. Correlations do not support a hypothesis that one group will be different from another; they would support a hypothesis that two variables are related.
- c. A small range only shows that the subjects had *similar* scores (number of cases solved), not that the control group had *lower* scores.
15. d is the answer. Following this procedure will ensure that every student in the population Susan wishes to study (first-year students at her university) will have an equal chance of being selected for participation in the experiment. (see Selecting Human Participants for Research)
- a. The use of one dorm will not give every first-year student an equal chance of being selected. Also, a particular dorm might house a certain kind of student. For example, the majority of students living in a dorm located next to the College of Agriculture might be agriculture majors who live there because of the convenient location. But Susan is interested in *all* first-year students, not just agriculture students.
- b. Some first-year students may not take introductory psychology. Therefore, first-year students do not all have an equal chance of being selected for the study.
- c. Some first-year students may not have a phone or a listed phone number.

16. *b* is the answer. The strongest correlation coefficient possible is 1.00. No other coefficient listed is closer to a perfect correlation than $-.99$. (see Correlation and Correlation Coefficients)
- a.* The strength and direction of a correlation are independent of each other. The positive or negative sign indicates the direction, and the number indicates the strength: the closer to 1.00, the stronger the correlation. As $-.99$ is closer to -1.00 than $+.75$ is to $+1.00$, $-.99$ is the stronger correlation.
- c, d.* You may have thought that a positive or negative .01 correlation coefficient represented a perfect correlation. However, a perfect correlation is $+1.00$ or -1.00 .
17. *b* is the answer. Measures of central tendency—the mean, median, and mode—describe the typical value in a data set around which the scores have a tendency to center. (see Measures of Central Tendency)
- a.* The standard deviation, a measure of variability, describes the average distance of scores from the mean of a data set.
- c.* The range, a measure of variability, is equal to the lowest score in a data set subtracted from the highest score.
- d.* Measures of central tendency do not affect the nature of a sample.
18. *c* is the answer. A negative correlation tells us that as one variable (seat-belt use) increases, the other variable (accident-related deaths) decreases. (see Correlation and Correlation Coefficients)
- a.* Correlations do not imply causation. Also, the variables here are the number of seat belts worn and the number of accident-related deaths, not the number of accidents.
- b.* This general statement does not follow from the information given and suggests causation. The information given specifies an inverse relationship between seat-belt laws and accident-related deaths.
- d.* Correlations do not imply causation. Also, the variable is the number of accident-related deaths, not the number of accidents.
19. *a* is the answer. The ethical guidelines followed by psychologists require that researchers describe the study well enough for potential participants to give their informed consent to be involved. (see Ethical Guidelines for Psychologists)
- b.* Participants should not expect a psychologist conducting research to give them counseling. Perhaps if it became clear that a participant was in distress the researcher could recommend that he or she see a clinical or counseling psychologist, but not all researchers are trained in counseling.
- c.* Psychoanalysis would be the job of a psychodynamic therapist, not a researcher conducting a study.
- d.* If an experiment requires that participants be misled, the researcher is required to disclose fully the reasoning behind the study after it is completed.
20. *a* is the answer. Behavior genetics is the study of how genes (nature) and the environment (nurture) influence behavior. (see Linkages: Psychological Research and Behavioral Genetics)
- b.* Genetic engineering and the field of behavior genetics are not the same thing. A genetic engineer, while interested in the role of genes in behavior, would use the results of genetics research to alter the gene set.
- c.* “Pop” psychology is short for popular psychology, which offers answers that are easy rather than well-supported by research. A “pop” psychologist would be more likely to write an advice book than to conduct genetic research.
- d.* Replicability means consistent results over many experiments. Replicating or repeating an outcome would most likely interest any scientist, but it does not describe the interest in problems that run in families.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 1 that you answered correctly.

ANSWERS TO MULTIPLE-CHOICE QUESTIONS

Circle the question numbers you answered correctly.

Sample Quiz 2

1. *a* is the answer. To think critically about the product offered, we should ask ourselves if there are other ways of interpreting the evidence. For example, were the people giving their testimonials because they were paid rather than because they used and benefited from the Run-O-Sizer? Are there other methods for achieving the same results? Could the photos have been altered to make the results look more dramatic? (see Thinking Critically About Psychology)
 - b.* Making your decision based on the testimonials would mean ignoring sources of information such as consumer magazines and fitness experts.
 - c.* The price is important to consider, but it says very little about the product's effectiveness or safety, or the likelihood you would use it.
 - d.* A guarantee might seem to make the purchase risk-free, but if the product is not worthwhile, you will have wasted time trying it and may still lose money. Therefore, a critical thinker will evaluate the claims made about the Run-O-Sizer before examining the guarantee.
2. *d* is the answer. (see Research Methods in Psychology)
 - a, b, c.* Measurement, understanding, reasoning, and critical thinking are processes involved in pursuing scientific goals, but are not goals specific to research methods.
3. *c* is the answer. To record the behavior of people during their usual activities is naturalistic observation. (see Naturalistic Observation: Watching Behavior)
 - a.* A case study is used to describe a rare condition completely; therefore, it would not describe average behaviors.
 - b.* A researcher would be unlikely to use an experiment, because behavior during a laboratory-simulated exam may be different from behavior during an actual exam.
 - d.* Using a survey would be a good way to find out how students describe their behavior during an exam, but it would not show what they look like, the number of times they shifted in their seats, and so on. In addition, their description might not match their behavior.
4. *a* is the answer. The subjects in the experimental group may report less depression because they think fluoxetine has medicinal value. (see The Experimental Method)
 - b.* Before the FDA approves a drug, a clear cause-effect relationship between the drug and the desired effect (decreased depression) must be demonstrated with very few side effects. Case studies are not used to detect cause-effect relationships; they describe a phenomenon of interest.
 - c.* The experimental design is incorrect. Both the experimental and the control groups should have been given pills. The experiment should be repeated using a double-blind design.
 - d.* Random samples are excellent for use in experiments and other types of research.
5. *c* is the answer. An operational definition, which will describe how depression is measured, can help the FDA determine whether patients experienced a change in level of depression. To understand why an operational definition is necessary, consider the following scenario. Joe, a subject in the experiment, is very, very depressed. After receiving the drug, he scores higher on the test. His test results show that he is still depressed, but not as depressed as he was prior to taking the drug. By using the test to operationally define depression, the FDA was able to measure a *change* in depression. If, however, the FDA had merely asked Joe how he felt, he might have responded that he was depressed both before and after taking the drug. (see Critical Thinking and Scientific Research)
 - a, b.* The independent variable is fluoxetine. Measuring the amount of a drug administered to the subjects is easy. It doesn't require an operational definition.
 - d.* There was no placebo.

6. *a* is the answer. The treatment administered to the experimental group is always the independent variable. (see The Experimental Method)
 - b*. The dependent variable is depression.
 - c*. The operational definition of depression is a low score on a questionnaire.
 - d*. Because the sample used was purely random, the presence of random variables has been controlled.
7. *c* is the answer. Experiments are used to conduct controlled research. Experimental and control groups are formed, and both groups are treated identically except the administration of the independent variable in the experimental group. At the end of the experiment, the dependent variable is measured in both groups. If there is a difference between the two groups on the dependent variable, that difference can only have been caused by the independent variable. (see The Experimental Method)
 - a, b, d*. Naturalistic observation, surveys, and case studies are all descriptive data collection methods.
8. *b* is the answer. Surveys are used to collect descriptive data on people's attitudes, beliefs, opinions, and behavioral intentions. (see Surveys: Looking at the Big Picture)
 - a*. Experiments are controlled methods of establishing a cause-effect relationship.
 - c*. Case studies are used to collect descriptive information from a particular individual, group, or situation. Case studies usually combine several forms of data collection—observations, interviews, tests, and analyses of written records. Case studies provide a close-up, in-depth view of subjects, whereas surveys paint a broad portrait.
 - d*. Naturalistic observation is used to collect behavioral information from the subjects' natural environment.
9. *c* is the answer. Multiple personality disorder is a rare problem, making a case study the most likely way to examine this hypothesis. (see Case Studies: Taking a Closer Look)
 - a*. Trying to improve students' study methods would not be something rare, and could be studied with an experiment.
 - b*. Experiencing an unpleasant odor could be easily manipulated in the laboratory with few negative consequences; therefore, this hypothesis could be studied in an experiment.
 - d*. All of the above are not true.
10. *b* is the answer. Experiments are used to study cause-effect relationships. (see Experiments: Exploring Cause and Effect)
 - a*. A case study focuses on one person in depth to document the person's behavior fully, his or her physical and psychological state, and so forth. It cannot determine cause and effect.
 - c*. Because naturalistic observation involves watching people in their usual environments, it cannot be used to find out what changes a person's reaction to a negative event. Not only would the researcher be unable to wait for at least two negative events to occur for each subject, but he or she also couldn't determine which variables might have caused a change (or lack of change) in the subject's behavior.
 - d*. A survey does not allow variables to be controlled to look for the effect on other variables.
11. *d* is the answer. Suppose an experimenter finds significant differences between the experimental group and the control group. If random variables exist in the experimental group but not the control group, for example, the experimenter cannot be sure what caused his results—the independent or the random variables. Random variables are a problem because they are difficult to control; sometimes they cannot be controlled. All of the variables listed would be difficult or costly for an experimenter to quantify and control. (see Random Variables)
12. *a* is the answer. A person with a rare condition is best studied in depth through a case study. (see Case Studies: Taking a Closer Look)
 - b*. An experiment could not be conducted to see if lightning causes unusual behavior; it would be wrong.
 - c*. A researcher wouldn't use naturalistic observation to gain understanding of a person with an unusual problem, because unobtrusively watching a person doesn't provide information about family background, health history, current physical condition, and so on.

- d.* To survey a person who is having trouble regulating her behavior and concentrating would be difficult, if not impossible. In addition, a survey includes more than one or a few participants because its purpose is to discover something about a group of people.
13. *d* is the answer. Having an equal chance of being selected for participation in a study would be impossible, or nearly so, for all the members of these populations. (see Selecting Human Participants for Research)
- a.* Contacting every human being on the face of the earth to solicit participation in the study would be impossible.
- b.* The researcher probably wouldn't be able to find all the rats in New York City to ensure that each had an equal chance of being selected as a subject.
- c.* Many past U.S. presidents are dead and therefore would not have an equal chance of participating in the study.
14. *a* is the answer. Two types of statistics are used: descriptive statistics are used to summarize data, and inferential statistics are used to analyze data in order to draw conclusions about research results. (see Statistical Analysis of Research Results)
- b.* Measuring the dependent variable is part of an experimental procedure. Statistics are used to describe and analyze experimental *results*.
- c.* Independent-variable manipulation is a part of experimental procedure. Statistics are used to describe and analyze experimental *results*.
- d.* Correlations do not yield cause-effect relationships.
15. *b* is the answer. 10 is the most frequently occurring score. (see Measures of Central Tendency)
- a.* The mean of this data set is 12. It is calculated by summing the values of all the scores and dividing by the number of scores.
- c.* The median of this data set is 11. It is the score that cuts the data set in half.
- d.* The range is 12. It is calculated by subtracting the lowest score from the highest score.
16. *b* is the answer. In a positive correlation, both variables *vary* in the same direction together; as one increases so does the other (and vice versa). (see Correlation and Correlation Coefficients)
- a.* A negative correlation tells us that as one variable increases, the other decreases.
- c, d.* Correlations do not imply causation. One can never conclude that one variable *causes* the other to change in any direction based on a correlation—regardless of its positive or negative value.
17. *b* is the answer. The average test scores were very low. Since the recruiter wants to find students with the highest scores, he needs the data set with the greatest number of scores that are very distant from the mean. The standard deviation is a measure of variability; it describes the average distance from the mean in a data set. If the standard deviation is large, then there will be a large number of extreme scores; this, in turn, means there is a large probability that some scores are very high. Therefore, the recruiter should look at the data sets that have the largest standard deviations to find students who scored very high on the intelligence test. (see Measures of Variability)
- a.* The range is also a measure of variability. If the range is large then the recruiter knows that at least one score in the data set is very low or very high. But the standard deviation takes into account more than two test scores and is a better measure of the probability that more than one high score exists in a data set.
- c.* The recruiter has already identified the mean, median, and mode—all measures of central tendency—for the data sets.
- d.* Operational definitions are used to describe ways of measuring a given variable (for example, anxiety).
18. *c* is the answer. A positive correlation indicates that as one variable increases, the other variable increases. This type of relationship supports the data; as alcohol consumption increases, so does decision-making time. (see Correlation and Correlation Coefficients)

- a, d.* A negative correlation indicates that as one variable increases, the other decreases. This relationship does not fit the data.
- b.* There is no such thing as a curvilinear correlation. Curvilinear correlations do not exist.
19. *d* is the answer. Psychologists follow ethical guidelines because they want their studies to benefit society, because specific guidelines are set forth by several organizations, and because undue stress and pain might become confounding variables in an experiment. (see Ethical Guidelines for Psychologists)
20. *a* is the answer. The studies used in such behavioral genetics research include adoption, family, and twin studies. (see Linkages: Psychological Research and Behavioral Genetics)
- b.* An experiment would be a controlled study in which, for example, participants were assigned to families; therefore, it would not be ethical.
- c.* Factor analysis is a correlational method used to identify variables, such as personality traits, that tend to occur together. Factor analysis would not help in determining what the relative effects of environment and genetics are.
- d.* A psychologist using naturalistic observation would watch and record behaviors, but could make no conclusions about the impact of heredity or environment on something like intelligence.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 2 that you answered correctly.

For each question you answered correctly, circle its number. (Quiz 1 numbers are not shaded; Quiz 2 numbers are shaded.) Are there patterns in the types of questions or the topics you got wrong that could direct your further study? Did you improve from Quiz 1 to Quiz 2?

CHAPTER 3

Biological Aspects of Psychology

MULTIPLE-CHOICE QUESTIONS

SAMPLE QUIZ 1

- Which of the following characteristics distinguishes neurons from other cells?
 - Mitochondria, which turn oxygen and glucose into usable energy
 - A nucleus that houses genetic information
 - A cell body
 - Axons and dendrites
- This is a story from the neuron kingdom. The king of the neurons wanted to be able to create action potentials at his will, so he decreed that certain substances would be under his control. When he wants action potentials to occur *immediately*, he should allow
 - neurotransmitters to flood into vesicles.
 - neurotransmitters to flood into dendrites.
 - sodium ions to rush into axons.
 - sodium ions to rush into synapses.
- Myelin serves what purpose in the nervous system?
 - It accelerates an action potential's movement.
 - It is a chemical that travels across the synapse.
 - It causes an inhibitory postsynaptic potential.
 - It causes an excitatory postsynaptic potential.
- A neuron fires or does not fire, depending on whether the depolarization of its interior environment reaches a certain level. This critical level is called the
 - point of no return.
 - threshold.
 - refractory period.
 - postsynaptic potential.

5. While you are spying on a neuron neighbor, you see an equal number of excitatory and inhibitory postsynaptic potentials reach the cell body near the axon. You know this will
 - a. cause an action potential.
 - b. cause neurotransmitters to be released.
 - c. keep the neuron from sending a message.
 - d. keep the neuron from receiving a message.
6. A woman was rushed into an emergency room with severely burned hands. She had picked up an iron because she couldn't tell it was hot and she currently doesn't feel pain from the burns. The neurologist who examined her concluded that the woman's _____ system was malfunctioning.
 - a. sensory
 - b. motor
 - c. autonomic
 - d. parasympathetic
7. Dr. Frankenstein has given up on creating a human and is trying to build King Kong's cousin. He forgot to install the motor nerves of the somatic system. What will Kong's kin be unable to do?
 - a. Lift skyscrapers
 - b. Hear people scream
 - c. Digest skyscrapers
 - d. See people run from him
8. Kalli finishes her exam and hurries home. When she arrives home, she slumps down on her bed to relax. As Kalli relaxes, her _____ nervous system becomes less active while her _____ nervous system becomes more active.
 - a. central; somatic
 - b. somatic; central
 - c. parasympathetic; sympathetic
 - d. sympathetic; parasympathetic
9. Our daily biological rhythms are governed by a structure called the
 - a. substantia nigra.
 - b. suprachiasmatic nuclei.
 - c. striatum.
 - d. thalamus.
10. The _____ is located in the hindbrain and helps to regulate blood pressure, breathing, and heart rate.
 - a. medulla
 - b. hypothalamus
 - c. thalamus
 - d. cerebellum
11. Kwan Li's auto accident caused her to have difficulty with her piano playing. She could no longer play even pieces that she knew well. When the doctors tested her, she also had difficulty tracking with her eyes the movement of a finger held in front of her face and difficulty in tracing drawings with a pen. Damage to Kwan Li's _____ would most likely cause such motor skill difficulties.
 - a. cerebellum
 - b. diencephalon
 - c. parietal lobe
 - d. occipital lobe
12. Broca's area and Wernicke's area are located in the _____ cerebral hemisphere and are involved in _____.
 - a. right. language
 - b. left. language
 - c. right. movement
 - d. left. biological rhythms
13. Derek has a tingling sensation in his left foot. Which area of the brain has most likely been affected?
 - a. left temporal lobe
 - b. left striatum
 - c. right frontal lobe
 - d. right parietal lobe

14. Which of the following is *not* a characteristic of our brains that would make complete recovery from brain damage difficult?
- Adult brains generally do not generate new neurons.
 - The brain, prior to damage, has millions of neural connections.
 - Glial cells eliminate damaged neurons.
 - Neurons cannot change their functions.
15. For drafting class Tasha must be able to draw three-dimensional views of various tools. Which cerebral hemisphere will most likely be activated while she completes this assignment?
- Right
 - Left
 - Both
 - Cannot be determined
16. When her vision is blocked by a screen, Sue cannot name objects by using only the sense of touch with her left hand, but she can do so with her right hand. Sue can use the sense of touch to retrieve a previously held object from among several choices using the left hand only or the right hand only. Which part of Sue's brain was most likely damaged?
- Hippocampus
 - Substantia nigra
 - Parietal lobe
 - Corpus callosum
17. A study found that rats raised in stimulating environments have more dendrites and synapses than rats raised in boring environments. This suggests that
- experience plays an important part in the structure and functioning of the brain.
 - genetic factors determine the basic pattern of connections of the brain.
 - synaptic plasticity is severely limited when it comes to repairing brain damage.
 - brain lateralization is more common in male rats.
18. A nurse has mixed up some test results on neurotransmitter function in several patients at the hospital where you work. To help her out, you tell her that the Alzheimer patient's chart will show too little _____ and the Parkinsonian patient's chart will show too little _____.
- dopamine, norepinephrine
 - dopamine, acetylcholine
 - acetylcholine, dopamine
 - acetylcholine, norepinephrine
19. Ted is trying to make a study sheet to help him learn the differences between neurotransmitters and hormones. Which of the following statements on his list is *not* correct?
- Neurotransmitters travel via the bloodstream and hormones travel across synapses.
 - Both hormones and neurotransmitters stimulate only those cells and organs that have receptors for them.
 - Hormones and neurotransmitters regulate complex behaviors and mental processes.
 - All of the above are correct.
20. A cold virus entered Isaac's body. A team of cells surrounded the unwanted virus cells like a S.W.A.T. team and destroyed them. Which of the following play the role of a S.W.A.T. team for our bodies?
- Central nervous system
 - Endocrine system
 - Immune system
 - Reflexes

Total Correct (See answer key) _____

SAMPLE QUIZ 2

Use this quiz to reassess your learning after taking Quiz 1 and reviewing the chapter.

1. One of the special features that enable neurons to communicate efficiently is
 - a. their structure.
 - b. their sensitive surface membranes.
 - c. their synapses.
 - d. all of the above.
2. Following is a conversation between two axons. Fill in the blanks. *Axon No. 1*: "Life is so dull. I have not been _____ all day." *Axon No. 2*: "Don't complain. I have it rough, too. Even with all of this (these) _____ wrapped around me, I can't seem to get my signals to the synapse fast enough for the boss."
 - a. depolarized, myelin
 - b. depolarized, receptors
 - c. polarized, sodium gates
 - d. polarized, vesicles
3. Pretend your class is demonstrating the roles of various cells and structures of a neuron. If you are playing the role of a positive ion participating in an action potential, you should
 - a. go in through an open gate in the axon.
 - b. run from the cell body to the end of the axon.
 - c. begin running from the cell body, but start slowing down at the end of the dendrite.
 - d. float across the synapse and bind with a receptor.
4. Scientists have discovered a virus that binds to postsynaptic receptors and prevents the reception of neurotransmitter signals. On which parts of nerve cells would this virus most likely be found?
 - a. Dendrites
 - b. Axons
 - c. Cell bodies
 - d. All of the above
5. A neurotransmitter is speeding across a synapse. Once it binds to another neuron, it will cause the postsynaptic membrane to hyperpolarize. To what kind of postsynaptic potential will this neurotransmitter contribute?
 - a. Excitatory
 - b. Inhibitory
 - c. Myelinated
 - d. Refracted
6. The spinal cord is part of the _____ system.
 - a. peripheral nervous
 - b. somatic
 - c. autonomic
 - d. central nervous
7. As you are waiting for a friend in a hospital waiting room, you overhear a doctor tell a worried spouse that her husband has a neurological problem. The nerves that carry signals to the muscles are not functioning. The _____ system has been damaged.
 - a. central
 - b. autonomic
 - c. somatic
 - d. sympathetic
8. Sarah is playing volleyball. She is running, hitting the ball, and shouting encouragement to her teammates. As a consequence, her heart rate is high, her breathing is rapid, and she is sweating. Which subdivision of her autonomic nervous system is activated?
 - a. parasympathetic
 - b. peripheral
 - c. somatic
 - d. sympathetic

9. A reflex
 - a. occurs without assistance from the brain.
 - b. involves the activity of afferent and efferent neurons.
 - c. is involuntary.
 - d. all of the above
10. People with severed spinal cords cannot receive sensory information from, or send signals to, the muscles below the level of damage because
 - a. the brain can no longer decipher incoming sensory information.
 - b. the information going to and from the brain must travel through the spinal cord.
 - c. the thalamus's relay station for sensory information always degenerates after spinal cord injuries.
 - d. None of the above are true.
11. Which two structures of the brain are particularly necessary if you are to stay awake and maintain attention during class?
 - a. Substantia nigra; striatum
 - b. Hypothalamus; suprachiasmatic nuclei
 - c. Cerebellum; cerebrum
 - d. Reticular formation; locus coeruleus
12. Conchita can meet a person or read the same story over and over for months but will never recall either. Which part of Conchita's brain was most likely damaged?
 - a. cerebellum
 - b. hippocampus
 - c. medulla
 - d. hypothalamus
13. The occipital lobe receives sensory information concerning
 - a. pain.
 - b. body movement.
 - c. vision.
 - d. body temperature.
14. Large parts of the cerebral cortex perform higher-level cognitive tasks, even though they are not directly involved with any particular function. These parts are called the
 - a. somatosensory cortex.
 - b. limbic system.
 - c. association cortex.
 - d. homunculus.
15. Which statement concerning nootropics is most accurate?
 - a. "Smart drugs" have been found to substantially enhance memory.
 - b. Nootropic drugs are a pseudoscientific fad.
 - c. Cognitive functioning is more likely to be positively influenced by behavior and environment than by any drug available today.
 - d. So far, scientists have not taken "smart drugs" seriously enough to begin a program of study.
16. Which of the following is *not* true? The corpus callosum
 - a. connects the two cerebral hemispheres.
 - b. contains many fibers.
 - c. is enlarged in cases of severe epilepsy.
 - d. allows the brain to function as a whole.
17. You have found an injured cat that cannot move the right side of its body very well. What kind of brain damage might explain the cat's condition?
 - a. A severed corpus callosum
 - b. Impaired functioning of the motor cortex in the left cerebral hemisphere
 - c. A dysfunctional hypothalamus
 - d. Impaired functioning of the somatosensory cortex in the right cerebral hemisphere

18. Kevin was so busy helping to carry children from a burning building that he did not feel any pain from the burns on his arms. His _____ neurotransmitters were most likely the reason for the modification of pain signals to his brain.
- glutamate
 - dopamine
 - endorphin
 - norepinephrine
19. When Mitch saw the woman who appeared to be drowning, he grabbed his life preserver ring and ran to save her. To prepare his body to run, Mitch's _____ released cortisol and other chemicals into his bloodstream.
- glands
 - neurotransmitter systems
 - synapses
 - target organs
20. Terry has an autoimmune disorder; therefore, the cells of Terry's immune system
- are attacking normal body cells.
 - are creating antibodies for viruses Terry hasn't encountered.
 - automatically create tumors.
 - automatically destroy tumors.

Total Correct (See answer key) _____

ANSWERS TO MULTIPLE-CHOICE QUESTIONS

Circle the question numbers you answered correctly.

Sample Quiz 1

1. *d* is the answer. A neuron has axons and dendrites. The sodium and calcium channels in axons and dendrites allow signals to travel their length—this is one special feature that allows neurons to communicate. (see Cells of the Nervous System)
a, b, c. All cells have a nucleus and a cell body as well as mitochondria, which turn oxygen and glucose into energy.

2. *c* is the answer. Action potentials in axons begin when gates open to admit positive ions, such as sodium. (see Action Potentials)
 - a.* Neurotransmitters are stored in vesicles; therefore, they could not flood in.
 - b.* Neurotransmitters bind with receptors on the postsynaptic cell, which could be a dendrite, but they don't flood into the dendrite. In addition, they may not eventually create an action potential because they could cause an inhibitory postsynaptic potential (IPSP).
 - d.* Sodium does not rush into the synapse; neurotransmitters do.
3. *a* is the answer. (see Action Potentials)
 - b.* A neurotransmitter travels across the synapse and fits into postsynaptic receptors.
 - c, d.* Myelin doesn't influence the nature of the postsynaptic potential.
4. *b* is the answer. A threshold is the point at which the neuron is sufficiently depolarized so that sodium gates open and sodium ions rush in, causing an action potential. (see Action Potentials)
 - a.* When threshold is reached, it is indeed a point of no return—the neuron will fire. However, this is not correct terminology.
 - c.* The refractory period is the rest period between action potentials, when the axon repolarizes itself.
 - d.* A postsynaptic potential occurs when the membrane potential of the postsynaptic cell is changed. It is one of many events that may lead up to depolarization of a neuron.
5. *c* is the answer. An equal number of excitatory and inhibitory signals will cancel each other out. (see Synapses and Communication Between Neurons)
 - a.* An action potential will occur if enough excitatory signals reach the cell body. In this situation, not enough have reached the cell body to override the number of inhibitory signals.
 - b.* Neurotransmitters are not released until an action potential occurs.
 - d.* The neuron *is* receiving messages in the form of excitatory and inhibitory postsynaptic potentials.
6. *a* is the answer. The sensory systems, such as vision, touch, pain, taste, hearing, and smell, provide information about the environment. (see Organization and Functions of the Nervous System)
 - b.* The motor system causes muscle movement.
 - c.* The autonomic system carries messages back and forth between the central nervous system and the body's organs and glands.
 - d.* The parasympathetic system is part of the autonomic system.
7. *a* is the answer. Without motor nerves to move the skeletal muscles, King Kong's cousin will not be able to move or pick up a rock, let alone lift a skyscraper. (see Organization and Functions of the Nervous System)
 - b.* The somatic system's sensory nerves will be able to carry auditory information to the brain.
 - c.* The autonomic nervous system will allow King Kong's cousin to digest skyscrapers. The autonomic system carries messages to the organs of the body, such as the stomach.
 - d.* The somatic system's sensory nerves will be able to carry visual information to the brain.
8. *d* is the answer. The sympathetic nervous system is becoming less active now that Kalli is not hurrying or worrying. The parasympathetic system is responsible for conserving energy and relaxing a person, so it is becoming more active. (see The Autonomic Nervous System)
 - a, b.* The central nervous system is no more activated when a person is relaxing than it is when the person is aroused. The somatic nervous system takes care of receiving information from the senses and sending instructions to the muscles.
 - c.* The parasympathetic system is the part of the autonomic nervous system that calms a person, so it is becoming more active. The sympathetic system activates the person as in the fight-or-flight response.
9. *b* is the answer. The suprachiasmatic nuclei is part of the hypothalamus that acts as a type of biological clock, governing the timing of many recurring bodily processes. (see The Forebrain)

- a.* The substantia nigra is part of the midbrain concerned with smooth initiation of movement.
 - c.* The striatum is also part of the midbrain and interacts with the substantia nigra.
 - d.* The thalamus processes and relays sensory information to different parts of the brain.
- 10. *a* is the answer. The medulla, located in the hindbrain, helps to regulate breathing and blood pressure. (see The Hindbrain)
 - b, c.* The hypothalamus and the thalamus are in the diencephalon, which is located in the forebrain.
 - d.* The cerebellum is located in the hindbrain, but it controls fine movement coordination.
- 11. *a* is the answer. The cerebellum controls well-rehearsed movements like piano playing and assists the eyes in tracking a moving object. (see The Hindbrain)
 - b.* The diencephalon is made up of the thalamus, which relays sensory information, and the hypothalamus, which regulates drives.
 - c.* The parietal lobe receives information from the skin senses, but it would not account for difficulty in memories of rehearsed movements or difficulty in tracking.
 - d.* The occipital lobe receives information from the eyes, but it would not account for difficulty in movement.
- 12. *b* is the answer. Broca's area and Wernicke's area, in the left cerebral hemisphere, are responsible for the mental organization, production, and comprehension of language. (see The Association Cortex)
 - a.* For most people the right side of the brain is less effective at tasks involving language.
 - c.* The motor cortex, found in the frontal lobe in *both* hemispheres, is involved in movement.
 - d.* The left hemisphere does include Broca's area and Wernicke's area, but they are not involved in biological rhythms. The suprachiasmatic nuclei in the hypothalamus control biological rhythms.
- 13. *d* is the answer. The right parietal lobe receives skin sense information from the body's left side. (see The Cerebral Cortex)
 - a.* The left temporal lobe is the location of Wernicke's area. It is involved in hearing and language.
 - b.* The striatum is part of the midbrain. Along with the substantia nigra, it is responsible for beginning a movement.
 - c.* The right frontal lobe would control the muscles for the left side of the body.
- 14. *d* is the answer. Neurons *can* change their functions and make new connections with other neurons; therefore, this is not a characteristic that would make recovery from brain damage difficult. (see Plasticity: Repairing Damage in the Central Nervous System)
 - a, b, c.* It is true that adult brain cells generally do not divide and generate new brain cells and that the brain has so many neural connections that exact replication following brain damage would be highly unlikely. Finally, glial cells do eliminate damaged brain cells before they have a chance to regenerate. Therefore, each of these *is* a characteristic making recovery from brain damage difficult.
- 15. *a* is the answer. The right hemisphere has better spatial and artistic abilities, which are important in a drafting assignment. (see The Divided Brain in a Unified Self)
 - b.* The left hemisphere has better logic and language abilities.
 - c, d.* The two hemispheres will not be equally activated in the completion of this task. Research has determined that certain tasks are performed more efficiently by one hemisphere than by another.
- 16. *d* is the answer. When the corpus callosum is cut, the two hemispheres are no longer joined. Without the corpus callosum, the information coming to the right side of Sue's brain (from her left hand) cannot reach the language centers on the left side of the brain. Sue can recognize the feel of the object because that task doesn't require help from the left hemisphere. (see The Divided Brain in the Unified Self)
 - a.* The hippocampus is responsible for helping to store new memories. Sue could remember what the object was, as evidenced by her ability to choose it by touch.
 - b.* The substantia nigra works with the striatum to help a person start moving. Sue doesn't have a problem with starting to move.

- c.* If Sue's parietal lobe were damaged, she would have trouble sensing touch, pressure, and temperature on her skin. Because she can choose the object, she must not have trouble with this lobe.
17. *a* is the answer. The study results indicated that the structures and functioning of the brain were altered simply by manipulating the rats' environments, and thus their experiences. (see Linkages: Human Development and the Changing Brain)
- b.* This statement is correct. However, genetic factors were not the focus of the study described in the question.
- c.* This statement is correct. However, synaptic plasticity was not the focus of the study.
- d.* Brain lateralization is the idea that certain tasks are performed more efficiently by one hemisphere than by the other. It is not more prevalent in male rats and has nothing to do with this study.
18. *c* is the answer. Degenerating acetylcholine neurons are associated with Alzheimer's disease, and low levels of dopamine are associated with Parkinson's disease. (see Three Classes of Neurotransmitters)
- a, b, d.* Decreased levels of dopamine are associated with Parkinson's disease; abnormal levels of norepinephrine are associated with depression; and degenerating cholinergic neurons are associated with Alzheimer's disease.
19. *a* is the answer. Neurotransmitters travel across synapses, and hormones travel via the bloodstream; therefore, statement *a* is incorrect. (see The Endocrine System: Coordinating the Internal World)
- b, c.* Both are true.
- d.* *a* is incorrect.
20. *c* is the answer. The immune system oversees the condition of the body. If it detects foreign cells, immune system cells surround and destroy them. (see The Immune System: Defending the Body)
- a.* The central nervous system guides all activity, but neurons in the CNS do not directly monitor or eradicate harmful invaders.
- b.* The endocrine system monitors levels of hormones in the bloodstream, but its cells do not find and eliminate foreign cells.
- d.* Although we do not have to consciously control our immune system in order for it to work, it is not a reflex. In a reflex, the spinal cord signals muscles to react to a stimulus; in immune system functioning, the cells locate and combat foreign cells.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 1 that you answered correctly.

ANSWERS TO MULTIPLE-CHOICE QUESTIONS

Circle the question numbers you answered correctly.

Sample Quiz 2

1. *d* is correct. A neuron's structure, its "excitable" surface membrane, and the minute gap between neurons are the three unique features that enable efficient signal communication. (see Cells of the Nervous System)
- a, b, c* each contribute to efficient communication, but *d* is the correct answer.
2. *a* is the answer. When an axon is at rest, it is polarized. Depolarization leads to action potentials. The bored axon with no action is polarized. Myelin speeds the action potential on its way. The second neuron, despite the myelin wrapped around its axon, cannot seem to get action potentials down the length of the axon to the synapse fast enough for the boss. (see Action Potentials)
- b.* Axons have receptors, but they do not affect conduction speed.
- c.* An axon at rest is polarized. All axons have sodium gates. They do not affect the speed at which the action potential travels down the axon.
- d.* An axon at rest is polarized. Vesicles are located at the very tip of the axon and do not influence the speed of an action potential.

3. *a* is the answer. Positive ions depolarize an axon by entering through gates in a chain reaction from one end of the axon to the other. (see Action Potentials)
 - b*. The sodium and calcium ions do not rush down the axon. Instead, like a line of dominoes pushed over, positive ions coming through one open gate cause the next gate to open (and the next, and the next) until one segment after another has been depolarized.
 - c*. The postsynaptic potential does dissipate as it reaches the cell body, but an action potential starts and finishes at the same rate.
 - d*. After an action potential has reached it, a neurotransmitter floats across a synapse to bind with a receptor.
4. *d* is the answer. Axons release neurotransmitters at synapses, and the most common arrangement is to have postsynaptic receptors on dendrites. However, postsynaptic receptors are also found on cell bodies and on axons (the axon of a second neuron can be postsynaptic to a presynaptic axon). (see Synapses and Communication Between Neurons)
5. *b* is the answer. An inhibitory postsynaptic potential (IPSP) makes it less likely the cell will fire. By making the cell more negative (hyperpolarized), more positive ions have to enter to cause an action potential. The first ions will only polarize it, or reset it; the next ions will build toward depolarizing it. (see Synapses and Communication Between Neurons)
 - a*. A neurotransmitter that causes a postsynaptic cell to be depolarized causes an excitatory potential.
 - c, d*. Myelinated and refracted are not terms associated with postsynaptic potentials. Myelin is an insulator that allows axons to send messages faster; refractory periods are the pauses between firings.
6. *d* is the answer. The central nervous system includes the brain and the spinal cord. (see Organization and Functions of the Nervous System)
 - a, b, c*. The peripheral system includes the somatic and autonomic systems.
7. *c* is the answer. The somatic system carries information from the senses to the central nervous system and carries signals from the central nervous system to the muscles that move the skeleton. (see The Somatic Nervous System)
 - a*. The central nervous system includes the brain and spinal cord. The brain makes decisions about how to move, but the somatic nervous system (part of the peripheral nervous system) carries these signals to the muscles.
 - b*. The autonomic system (part of the peripheral nervous system) carries messages back and forth between the central nervous system and the body's organs and glands.
 - d*. The sympathetic system is part of the autonomic system (it controls the automatic functions of the body, not voluntary skeletal muscle movement).
8. *d* is the answer. The sympathetic system of the autonomic nervous system activates the body. (see The Autonomic Nervous System)
 - a*. The parasympathetic system of the autonomic nervous system calms the body.
 - b*. The peripheral nervous system has two branches: the somatic and autonomic. It is not a subdivision of the autonomic.
 - c*. The somatic nervous system is the branch of the peripheral nervous system controlling voluntary movement and receiving sensory information. It is not a subdivision of the autonomic.
9. *d* is the answer. A reflex can occur entirely within the spinal cord; it involves afferent and efferent neurons; and it is involuntary. (see The Spinal Cord)
10. *b* is the answer. Information about the environment travels through the spinal cord on its way to the brain. In addition, any directions that the brain sends to the skeletal muscles must pass through the spinal cord. If the spinal cord is severed, information cannot travel between the brain and any destination below the severed section of the spinal cord. (see The Spinal Cord)
 - a, c*. Damage to the spinal cord will not injure the brain. The brain may not be as active because it does not receive as much information as it did prior to the spinal cord's injury, but it would still be capable of handling that information.

- d.* *b* is the answer.
11. *d* is the answer. The reticular formation in the hindbrain is important in keeping an individual awake. Within the reticular formation is a small structure, the locus coeruleus, which is involved in directing attention. (see The Hindbrain)
- a.* The substantia nigra and striatum are structures of the midbrain involved in the initiation of movement.
- b.* The hypothalamus in the forebrain is involved in motivated behaviors, such as hunger, thirst, and sex drives. Within the hypothalamus is the suprachiasmatic nuclei, our internal clock regulating biological rhythms.
- c.* The cerebellum is a part of the hindbrain involved in fine motor movement. The cerebrum is the largest part of the forebrain containing other brain structures.
12. *b* is the answer. Damage to the hippocampus causes the inability to form new memories. Conchita cannot form new memories for people or stories. (see The Forebrain)
- a.* The cerebellum controls movement, not memory.
- c.* The medulla regulates vital functions like heart rate and breathing.
- d.* The hypothalamus regulates hunger, thirst, and sex drives, not memory.
13. *c* is the answer. The sensory cortex found in the occipital lobe receives information concerning vision. (see The Cerebral Cortex)
- a.* The thalamus, found in the forebrain, relays pain signals from the spinal cord and the senses to upper levels in the brain.
- b.* The motor cortex, found in the frontal lobe, is involved in movement.
- d.* The parietal lobe receives information about temperature from the skin.
14. *c* is the answer. The association cortex, involved in higher mental abilities, often receives information from more than one sense or combines sensory and motor information. (see The Cerebral Cortex)
- a.* The somatosensory cortex, in the parietal lobe, receives information about touch, pain, and temperature.
- b.* The limbic system is a series of interconnected structures that play an important role in regulating emotion and memory.
- d.* *Homunculus* is the term for the pattern of neighboring skin sensations corresponding to neighboring parts of the somatosensory cortex.
15. *c* is the answer. What is known at this time is that we may be able to reduce the risk of degenerative brain disorder by keeping the brain active and increasing cerebral blood flow by using the mind. (see Thinking Critically: Are There Drugs That Can Make You Smarter?)
- a.* Research evidence is mixed. There have been no definite conclusions about the overall efficacy of "smart drugs."
- b.* The available drugs *do* have some positive influences on mental abilities, but the effects are minimal.
- d.* A number of scientists are conducting research in this area, as evidenced by the numerous references in the text.
16. *c* is the answer. The corpus callosum, a massive bundle of fibers, connects the two cerebral hemispheres. It has been surgically severed, not enlarged, in cases of severe epilepsy to decrease the spread of electrical seizures. (see Plasticity: Repairing Damage in the Central Nervous System)
- a, b, d.* All are true.
17. *b* is the answer. The motor cortex in the left hemisphere controls the movement of the body's right side. (see The Divided Brain in a Unified Self)
- a.* A severed corpus callosum will only prevent the right hemisphere from communicating with the left hemisphere.

- c. A damaged hypothalamus causes malfunction in eating, drinking, sex drives, and, possibly, emotional responses.
 - d. The right somatosensory cortex receives sensory information from the body's left side. Thus, motor functioning will not be impaired.
18. *c* is the answer. Endorphins modulate pain. (see The Endocrine System: Coordinating the Internal World)
- a. The neurotransmitter glutamate is involved in memory.
 - b. The neurotransmitter dopamine is involved in movement and reward.
 - d. When norepinephrine acts as a neurotransmitter, it is involved in sleep, learning, and mood regulation.
19. *a* is the answer. Glands release hormones such as cortisol into the bloodstream. (see The Endocrine System: Coordinating the Internal World)
- b. Neurotransmitter systems are groups of neurons using the same neurotransmitter.
 - c. Synapses are the gaps between neurons; they do not release hormones into the bloodstream.
 - d. Target organs have cells with receptors for hormones. They receive, not send, the hormones.
20. *a* is the answer. (see The Immune System: Defending the Body)
- b. Antibodies would not be created if a virus hadn't entered the body.
 - c. The immune system does not create tumors.
 - d. When the immune system is working properly, it will attack tumor cells. In an autoimmune disorder, the immune system is attacking the regular cells of the body, including brain cells.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 2 that you answered correctly.

For each question you answered correctly, circle its number. (Quiz 1 numbers are not shaded; Quiz 2 numbers are shaded.) Are there patterns in the types of questions or the topics you got wrong that could direct your further study? Did you improve from Quiz 1 to Quiz 2?

CHAPTER 4

Sensation

MULTIPLE-CHOICE QUESTIONS

SAMPLE QUIZ 1

1. When Ali first had corrective braces put on his teeth, the pressure and tension were very uncomfortable. Now, however, he barely notices his braces. Why?
 - a. Since the pressure is constant, his sensory receptors have adapted.
 - b. Stimulation of a sensory nerve provides codes for only one sense.
 - c. There are no free nerve endings in Ali's mouth.
 - d. His transduction has been altered by the introduction of the braces.
2. What is *not* necessary for sound?
 - a. Airborne chemicals
 - b. A medium, such as air
 - c. Fluctuations in the pressure of a medium
 - d. Vibrations of an object
3. Ashanti cannot hear. All of the structures in his hearing system work, except for those that transduce the sound waves. Ashanti's _____ do not work; therefore, he has _____ deafness.
 - a. hair cells; nerve
 - b. hammer, anvil, and stapes bones; conduction

- c. semicircular canals; conduction
 - d. tympanic membranes; nerve
4. If the place theory is true, which of the following would cause the *least* amount of auditory impairment?
- a. Sitting in front of the speakers at a rock concert
 - b. Hearing a pure tone with a very high amplitude
 - c. Working in a factory where there are many noisy machines
 - d. Listening to Bach at full volume over your headphones
5. A scientist is preparing to study language processing in deaf individuals and hearing individuals. The brain regions he will be investigating are
- a. on the right side for deaf individuals and the left side for hearing individuals.
 - b. on the left side for deaf individuals and the right side for hearing individuals.
 - c. very susceptible to individual differences in hearing individuals and subject to the type of deficit in deaf individuals.
 - d. in the same locations whether the individuals can hear or are deaf.
6. Which of the following structures is *not* necessary for the transduction of light energy?
- a. Photoreceptors
 - b. Rods and cones
 - c. Visual cortical cells
 - d. Photopigments
7. A villain is trying to obliterate the visual system of his opponent. If he destroys _____, the opponent will be unable to see color.
- a. rhodopsin
 - b. rods
 - c. iodopsin
 - d. photoreceptors outside the fovea
8. Which of the following would cause the least amount of lateral inhibition to occur?
- a. Looking at a spider web covered with dew in the morning sun
 - b. Looking at a zebra's black and white stripes
 - c. Looking at a green refrigerator's surface
 - d. Looking at the pattern of light coming through window blinds
9. While Becky watched a basketball game on TV, Cindy asked her, "Is this OK for dinner?" Becky didn't look away from the game and thought, based on her peripheral vision, that Cindy held up a TV dinner, so she said, "Sure." Only when Cindy served Becky a plate of brussel sprouts did Becky realize that her visual acuity wasn't very good because she was relying primarily on _____.
- a. bipolar cells
 - b. cones
 - c. ganglion cells
 - d. rods
10. Which theory best explains the sensation of color?
- a. Trichromatic
 - b. Opponent-process
 - c. Young-Helmholtz
 - d. All of the above
11. A projection-screen TV has a separate box that aims green, red, and blue lights at the screen. Because the TV shows a full range of colors by combining the green, red, and blue lights in differing amounts, it fits best with the _____ theory of color vision.
- a. convergence
 - b. frequency-matching
 - c. opponent-process
 - d. trichromatic

12. Roxanne is responsible for teaching a new student how to do the stage lighting for their school's play. What should Roxanne tell the student?
 - a. Mixing colors for lights is identical to the process used for mixing paint.
 - b. Mixing two different colors of light produces a darker color.
 - c. Mixing two different colors of light is called subtractive color mixing.
 - d. Mixing all possible colors of lights produces a white light.
13. Which of the following is true?
 - a. Fibers from the inside half of each retina cross to the right side of the brain.
 - b. Fibers from the outside half of each retina cross to the right side of the brain.
 - c. Fibers from the inside half of each retina cross to the opposite side of the brain.
 - d. Fibers from the outside half of each retina cross to the opposite side of the brain.
14. Which sense does not send information through the thalamus on its way to the cortex?
 - a. Hearing
 - b. Vision
 - c. Olfaction
 - d. Somatosensory
15. Which of the following can alter the flavor of food?
 - a. Texture
 - b. Smell
 - c. Temperature
 - d. All of the above
16. In a biology class, Samantha rated solutions on how salty, sweet, or sour each was. Samantha most likely has taken a test of
 - a. analgesia.
 - b. gustation.
 - c. kinesthesia.
 - d. vestibulation.
17. The nerves that signal what is touching Gary's face are firing very, very rapidly. Which of the following most likely happened?
 - a. He was just punched in the mouth.
 - b. He was just kissed on the cheek.
 - c. He just took a drink of water.
 - d. A fly just landed on his nose.
18. Marina hit her elbow on the doorway. According to the gate control theory, in order to reduce the amount of pain she is feeling, Marina should
 - a. use the image of a closing gate to give herself the expectation that the pain will end.
 - b. rub the sore area.
 - c. think about anything other than the pain.
 - d. do any of the above.
19. Ally has lost her kinesthetic sense. Ally will most likely be unable to
 - a. be sure her hand is raised without looking at it.
 - b. detect the flavor of her ice cream cone.
 - c. feel the warmth of the sun on her face.
 - d. respond to pain.
20. Kareem has overstimulated his vestibular sense. Which of the following is the most likely result of this overstimulation?
 - a. Difficulty judging distances
 - b. Dizziness
 - c. Incorrect feedback from joints and tendons
 - d. Overarousal of the autonomic nervous system

Total Correct (See answer key) _____

SAMPLE QUIZ 2

Use this quiz to reassess your learning after taking Quiz 1 and reviewing the chapter.

1. Ben is undergoing an experimental treatment that electrically stimulates the hair cells on the organ of Corti. According to the doctrine of specific nerve energies.
 - a. Ben's auditory neurons will fire at one specific rate.
 - b. Ben's proprioceptive nerves will be activated.
 - c. Ben will feel a touch.
 - d. Ben will hear sounds.
2. The pitch of a dog whistle is so high that humans cannot hear it. What physical dimension of sound would describe such a high pitch?
 - a. A waveform with a very high frequency
 - b. A waveform with a very low frequency
 - c. A waveform with a very high amplitude
 - d. A waveform with a very low amplitude
3. When Adriana pushes forward on the backs of her pinnas near her scalp, she notices that she can no longer tell where a high-pitched sound is coming from. Adriana's action has directly affected her
 - a. accessory structures.
 - b. cochlea.
 - c. timbre.
 - d. transduction mechanisms.
4. Conduction deafness is related to problems with
 - a. the hair cells of the basilar membrane.
 - b. the auditory nerve.
 - c. the malleus (hammer), incus (anvil), and stapes (stirrup).
 - d. the pinna.
5. Which theory suggests that pitch is determined by the location of movement along the basilar membrane?
 - a. The place theory
 - b. The characteristic-frequency theory
 - c. The frequency-matching theory
 - d. The volley theory
6. It is too dim for Carly to see what she is reading; therefore, she should _____ by turning on a lamp.
 - a. increase the light intensity
 - b. increase the light wavelength
 - c. decrease the light intensity
 - d. decrease the light wavelength
7. Rhoda, who is visiting her sister, just turned out the bathroom light and has to grope along the wall to feel her way back to the bedroom. After being in bed again for about forty-five minutes, she realizes that she can see well. Why?
 - a. Ganglion cells have been activated.
 - b. Enough photopigments in her rods have been synthesized.
 - c. The muscles that control her lenses have adapted to the dark.
 - d. The dendrites in her optic nerve have finally resynthesized.
8. Leslie is convinced that her roommate has horrible taste in color combinations. How else could she wear forest green slacks and an olive green sweater and not be bothered by the clash of the two shades of green? An alternative explanation is that Leslie's roommate may
 - a. have only two of the three color pigments in her cones.
 - b. be insensitive to light wavelength.
 - c. have different genes for cone pigments.
 - d. have no iodopsin in her cones.

9. The process of lateral inhibition allows the brain to see
 - a. color.
 - b. black and white.
 - c. more distinct contrasts in stimuli.
 - d. movement.
10. A villain is working feverishly in his laboratory to devise a way of preventing visual transduction. Which of the following methods would work?
 - a. Destroy all the photopigments in a person's eye.
 - b. Remove the lateral geniculate nucleus.
 - c. Uncross the optic nerve at the optic chiasm.
 - d. All of the above will prevent transduction.
11. Evelyn tried on a pair of sunglasses with red lenses. After wearing them for a few minutes, Evelyn took them off and realized that everything she looked at now had a green tint. The cells directly responsible for this afterimage were Evelyn's
 - a. cones.
 - b. bipolar cells.
 - c. ganglion cells.
 - d. rods.
12. The theory that best explains the afterimage seen by Evelyn is the _____ theory.
 - a. computational
 - b. opponent-process
 - c. trichromatic
 - d. volley
13. Michelle is an advertising executive. She wants her staff to create purer colors in the print ad they are working on. What will they have to do?
 - a. Alter the ad's hue.
 - b. Saturate the ad's colors.
 - c. Increase the ad's brightness.
 - d. Add a red tint to all green objects in the ad.
14. Your right visual cortex can "see" a mosquito biting one of your hands. If your right hand is in only your right visual field and the left is in only the left visual field, which hand will swat the mosquito?
 - a. The right
 - b. The left
 - c. Cannot be determined
15. Neural activity concerning an object that Maria has in her visual field has reached her lateral geniculate nucleus (LGN). A neuron in her LGN is most likely responding to the incoming information by
 - a. sending a different message to indicate which side of the visual field the object is in.
 - b. sending information to ganglion cells.
 - c. combining information about types of lines, colors, and the distance of the object into one message.
 - d. sending information about one aspect of the object, such as its depth.
16. When Pete bought a hot dog and fries at a street festival, the smell suddenly brought back memories of playing baseball for his adoring fans. The memory was most likely activated because his nose
 - a. sends its messages to the thalamus, which is connected to the olfactory network.
 - b. sends its messages to the olfactory bulb, which is connected to the amygdala.
 - c. causes papillae to become activated.
 - d. causes the basilar membrane to become activated.
17. Andre's papillae do not work. Which of the following statements is Andre most likely to make?
 - a. "I miss the feeling of a hot shower on my skin."
 - b. "Green and red both look gray to me."
 - c. "I couldn't smell the toast burning."

- d. "Nothing tastes right any more."
18. There is a new website advertising a pheromone product for men that "will have women making eye contact, flirting with, and even coming up and introducing themselves to you!" This product would most likely be a
- tape of music with hidden messages.
 - drug that could be slipped into someone's drink.
 - gas that would alter a man's voice.
 - cologne that a man would put on his body.
19. At a track and field competition, Paige pulls a muscle on her best discus throw of the season, but in all the excitement of her school's win, she does not experience much pain from the injury. Paige's lessened pain could be due to
- activated A-delta fibers.
 - activated C fibers.
 - a higher-than-usual naloxone level.
 - a higher-than-usual endorphin level.
20. Excellent proprioception would be required for which of the following careers?
- Chef
 - Wine taster
 - Acrobat
 - Musician

Total Correct (See answer key) _____

ANSWERS TO MULTIPLE-CHOICE QUESTIONS

Circle the question numbers you answered correctly.

Sample Quiz 1

1. *a* is the answer. A constant level of stimulation usually produces adaptation, a process through which responsiveness to an unchanging stimulus decreases over time. (see Sensory Systems)
- b*. This statement is true, but it refers to the idea that specific sensory nerves serve specific senses.
- c*. Many types of nerve endings are involved in the somatic senses.

- d.* Transduction is the process of converting environmental signals into neural signals. Braces would not interfere with transduction; they would just produce another sensation to be transduced.
2. *a* is the answer. Airborne chemicals are detected by olfaction, the sense of smell. (see Sound)
- b, c, d.* Together these form the definition of sound. Sound is the result of repetitive fluctuations in the pressure of a medium, such as air, produced by the vibrations of an object.
3. *a* is the answer. Hair cells are the transduction mechanisms for hearing; if they or the auditory nerve malfunction, nerve deafness results (see The Ear)
- b.* The hammer (malleus), anvil (incus), and stirrup (stapes) are accessory structures. If these middle-ear bones are fused, conduction deafness results.
- c.* The semicircular canals are the parts of the inner ear used for the vestibular sense.
- d.* Tympanic membranes (eardrums) send vibrations to the bones of the middle ear; they do not transduce sound waves.
4. *b* is the answer. A very pure tone has only one frequency. According to the place theory, a specific frequency will cause a specific place on the basilar membrane to move. A damaging pure tone would therefore cause damage to only one location. (see Coding Intensity and Frequency)
- a, d.* Both rock and orchestral music would be made up of many frequencies, thus causing damage all along the basilar membrane.
- c.* Machinery noise consists of many frequencies, thus causing damage all along the basilar membrane.
5. *d* is the answer. Both hearing and deaf individuals process language in the same regions of the brain. (see Auditory Pathways and Representations)
- a, b.* There is no lateralization associated with language processing in deaf versus hearing individuals.
- c.* Locations of sensory processing are pretty similar across individual members of a species.
6. *c* is the answer. Transduction is the conversion of stimulus energy into neural energy. This process occurs before information reaches the central nervous system. Therefore, the visual cortical cells in the brain receive already transduced information about the world. (see Converting Light into Images)
- a, b, d.* Visual transduction takes place at the photoreceptors (rods and cones) in the retina. Photopigments in the rods and cones break apart when stimulated by light, causing changes in membrane potential. A change in membrane potential is the first step toward neural activity.
7. *c* is the answer. Iodopsin is the photopigment in cones that initiates the transduction process. If this substance were destroyed, transduction would not occur and color vision would be impossible. (see Converting Light into Images)
- a, b.* Rods contain the photopigment rhodopsin. Rods detect black and white. Destroying rhodopsin would not destroy color vision.
- d.* The photoreceptors outside of the fovea are rods, which detect black and white.
8. *c* is the answer. Lateral inhibition occurs when there are many contrasts in visual stimuli, such as stripes or patterns of light and dark. The surface of a refrigerator does not feature much contrast. (see Converting Light into Images)
- a.* The edges of the lines in the web would be seen as differences between light and dark, causing a great deal of lateral inhibition.
- b.* The edges of a zebra's stripes would be seen as differences between light and dark, causing a great deal of lateral inhibition.
- d.* The pattern of light coming through the blinds would create strips of dark next to strips of light. The contrast would cause a great deal of lateral inhibition.
9. *d* is the answer. Rods are predominant in the periphery of the retina. If Becky uses peripheral vision, her acuity will be poorer. (see Converting Light into Images)
- a, c.* Bipolar and ganglion cells receive information from the rods and cones; the lack of information from the cones causes the poor vision.

- b.* Cones are located primarily in the fovea, or center, of the retina and are responsible for its high visual acuity.
10. *d* is the answer. Both the trichromatic theory (also known as the Young-Helmholtz theory) and the opponent-process theory are needed to account for the complexity of visual sensations of color. (see Seeing Color)
11. *d* is the answer. The trichromatic theory proposes that combining three colors of light will produce any other color. (see Seeing Color)
- a.* Convergence is the arrangement whereby bipolar cells receive information from many photoreceptors; it isn't a theory of color vision.
- b.* Frequency-matching theory is a theory of hearing which states that the firing rate of a neuron will match the frequency of a sound wave.
- c.* The opponent-process theory of color vision proposes that colors in pairs inhibit each other. Therefore, if red is activated in one pair, green will be inhibited in that pair.
12. *d* is the answer. Mixing lights is called additive color mixing. The more colors of light you add, the closer the resulting color is to white. (see Seeing Color)
- a.* Mixing paint is called subtractive color mixing. The more colors of paint you add, the darker the color becomes. This occurs because the two paints absorb, or subtract, more wavelengths of light than either color can alone.
- b.* Mixing two colors of light will always produce a lighter, not a darker, color.
- c.* Mixing paint, not light, is called subtractive color mixing.
13. *c* is the answer. Fibers from the inside half of each retina cross to the opposite side of the brain at the optic chiasm. (see Visual Pathways)
- a.* Only fibers from the inside half of the left retina cross to the right side of the brain.
- b, d.* Fibers from the outside half of the retinas never cross to the opposite side of the brain.
14. *c* is the answer. Nerves that carry information about smell leave the nose and travel to the olfactory bulb. Axons leaving the olfactory bulb travel to many parts of the brain, especially to the amygdala. (see Olfaction)
- a, b, d.* Nerves carrying information about hearing, vision, and touch do travel through the thalamus.
15. *d* is the answer. Texture, smell, and temperature all contribute to food's flavor. (see Smell, Taste, and Flavor)
16. *b* is the answer. Gustation is the sense of taste. (see Gustation)
- a.* Analgesia is the lack of a pain sensation in response to a usually painful stimulus.
- c.* Kinesthesia is our sense of where our body parts are in relation to one another.
- d.* Vestibulation is not a term. You may have been thinking of the vestibular sense, but that sense provides information about our head position, not taste.
17. *a* is the answer. The intensity or heaviness of an object touching the skin is coded by the number of active neurons as well as by the speed with which they are firing. Many of Gary's neurons are firing rapidly, so the touch must be heavy. Getting punched in the mouth is the heaviest touch among the choices. (see Touch and Temperature)
- b, c, d.* A kiss on the cheek, the feel of a glass against one's lips, and the feel of a fly on one's nose would cause only a few neurons to be active, and they would not fire very rapidly.
18. *b* is the answer. According to the gate control theory of pain, other sensations can compete with the pain sensations for the pathways to the brain. If Marina rubs her elbow, the rubbing may overpower some of the pain sensations and thereby reduce her pain. (see Pain)
- a.* An image of a closing gate might help Marina reduce her pain, but visualizations are not covered in the gate control theory. The gate control theory states that signals coming up the spinal cord or down from the brain may block the pain sensations.

- c. Thinking about something else may reduce Marina's pain, but the gate control theory does not address this.
- d. Only *b* is correct.
19. *a* is the answer. Kinesthesia gives us knowledge of the position of our body parts by sending information from our muscles and joints. (see Proprioception)
- b*. Gustation and olfaction would allow Ally to detect ice cream flavors.
- c, d*. The feeling of warmth on skin and responding to pain are part of the somatosensory systems, but are not kinesthetic senses.
20. *b* is the answer. The vestibular sense informs us about the position of our head. If Kareem has overstimulated this sense, perhaps by spinning around in a circle, he will most likely be dizzy. (see Proprioception)
- a*. Difficulty judging distances might occur if the visual system were affected.
- c*. Incorrect feedback from joints and tendons would indicate that the kinesthetic sense is malfunctioning.
- d*. Overarousal of the autonomic nervous system would not result from vestibular stimulation. The autonomic nervous system activates or calms the automatic processes in the body like heart rate and digestion. Overstimulation might result in some arousal, but not overarousal.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 1 that you answered correctly.

ANSWERS TO MULTIPLE-CHOICE QUESTIONS

Circle the question numbers you answered correctly.

Sample Quiz 2

1. *d* is the answer. The doctrine of specific nerve energies states that a sensory nerve can only code information for that sense. The hair cells on the organ of Corti transduce sound waves; therefore, any stimulation will be perceived as sounds. (see The Problem of Coding)
- a*. The auditory neurons might fire at different rates, depending on how much stimulation they are receiving.
- b, c*. The proprioceptive and touch senses are unrelated to the hair cells on the organ of Corti.
2. *a* is the answer. A very high frequency will produce a very high-pitched sound. (see Sound)
- b*. A very low frequency will produce a very low-pitched sound.
- c*. A very high amplitude will produce a very loud sound.
- d*. A very low amplitude will produce a very soft sound.
3. *a* is the answer. The pinnas (outer ears) are accessory structures; they modify the sound waves entering the ears. (see The Ear)
- b*. The cochlea is in the inner ear and would not be directly affected by Adriana's action.
- c*. Timbre is a quality of sound not related to the pinnas.
- d*. The transduction mechanisms for hearing are in the cochlea and would not be directly affected by movement of the pinnas.
4. *c* is the answer. Conduction deafness is caused by improper vibration in the malleus (hammer), incus (anvil), and stapes (stirrup). Onset usually occurs with increasing age when the bones begin to fuse together, preventing their movement. (see The Ear)
- a*. Damage to the hair cells of the basilar membrane results in nerve deafness.
- b*. Damage to the auditory nerve results in nerve deafness.
- d*. Depending on its severity, damage to the pinna may not harm hearing.

5. *a* is the answer. According to the place theory, the location of movement along the basilar membrane determines the pitch that we hear. (see Coding Intensity and Frequency)
 - b*. There is no such thing as the characteristic-frequency theory.
 - c, d*. The frequency-matching or volley theory suggests that the rate of neuronal firing in the auditory nerve matches the frequency of the sound.
6. *a* is the answer. Light intensity determines brightness. Carly should increase intensity to increase brightness. (see Light)
 - b, d*. Wavelength determines color.
 - c*. Decreasing light intensity would dim the light.
7. *b* is the answer. The rods, which are photoreceptors in the retina, allow us to see well in the dark. When the lights are first turned out, the rods must synthesize photopigments. This process takes between a half-hour and forty-five minutes. (see Converting Light into Images)
 - a*. Ganglion cells receive information from both rods and cones, but it is the rods that are responsible for dark adaptation.
 - c*. The muscles of the lenses do help us to focus on objects in the environment. However, the level of light in the environment does not affect the efficiency of these muscles.
 - d*. Dendrites are fibers that are permanent fixtures. They do not have to be resynthesized in any way.
8. *c* is the answer. There can be variations in the genes for middle wavelength cones, those that detect green. These variants have different sensitivities, so the same shade of green may look different to people with different genes. (see Seeing Color)
 - a*. If the roommate has only two of the three types of iodopsin, she would be described as colorblind. The question indicates that the roommate has trouble discriminating among different shades of the same color, not among different colors.
 - b*. The physical dimension of light wavelength produces the basic sensation of a certain color. The roommate is seeing a color and thus is processing light wavelengths.
 - d*. If the roommate's cones had no iodopsin, she could not experience color.
9. *c* is the answer. Lateral inhibition occurs when a cell with the greatest stimulation (cell number one) causes a reduction in activity in the surrounding cells (cells two through five). This will cause the brain to receive information indicating that the receptive field of cell one contains much more light than the receptive fields of cells two through five—in other words, that there is a light region next to a dark region. Therefore, lateral inhibition codes for contrast in the environment. (see Converting Light into Images)
 - a*. Cones detect color information.
 - b*. Rods detect black-and-white information.
 - d*. Specialized cells in the cortex detect movement.
10. *a* is the answer. Visual transduction occurs at the retina's receptors, called rods and cones. Photopigments in the rods and cones break apart when stimulated by light and cause changes in membrane potential. (see Converting Light into Images)
 - b*. Removal of the lateral geniculate nucleus would impair vision but not the transduction process.
 - c*. Uncrossing the optic nerve at the optic chiasm would change the way we see the world, but it would not impair transduction.
 - d*. Only *a* is the answer.
11. *c* is the answer. Ganglion cells have a center-surround receptive field that responds to opponent colors. Red or green, blue or yellow, and white or black are the opposing colors, only one of which can be signaled at a time. After one stops being stimulated, the other is activated, which creates afterimages. (see Seeing Color)
 - a*. Cones are responsible for color vision, but are not set up in opposing pairs to create afterimages.

- b.* Bipolar cells receive information from rods and cones, but do not have receptive fields responding to opponent colors.
- d.* Rods are responsible for black-and-white differentiation and cannot create afterimages.
12. *b* is the answer. The opponent-process theory explains afterimages. When one color in a pair has been inhibited, it will “overreact” and become activated when the other color is no longer stimulated. (see Seeing Color)
- a.* There is no such thing as a computational theory of color vision.
- c.* Trichromatic theory cannot explain afterimages; it describes how three colors can be combined to create all colors.
- d.* Volley theory is another term for the frequency-matching theory of hearing.
13. *b* is the answer. A saturated color will appear pure and vibrant. (see Seeing Color)
- a.* If Michelle changes the hues, she will change the colors but not necessarily their pureness.
- c.* Increasing the ad’s brightness will not increase the colors’ pureness.
- d.* Mixing two opponent colors will produce grey.
14. *a* is the answer. Your right hand will swat the mosquito. Information in the right visual cortex comes from the right sides of both eyes after coming from the left environment. Therefore, the mosquito is on your left hand and the right hand will swat it. (see Visual Pathways)
- b.* If the mosquito were on your right hand, then the left visual cortex, not the right, would receive the information.
- c.* It can be determined that *a* is the answer.
15. *d* is the answer. The LGN consists of layers of neurons that respond to different types of stimuli. Separate aspects of visual information are handled by parallel processing systems. Therefore, one neuron is responsible for depth information, another is responsible for color, and so on, and all work simultaneously. (see Visual Pathways)
- a.* The LGN has a complete map of the retina, and hence, the visual field. Neighboring cells respond to neighboring areas of the retina; therefore, they do not need to send another type of signal to indicate the area to which they are responding.
- b.* The ganglion cells send information to the thalamus, specifically the region known as the LGN.
- c.* There does not appear to be a place in the LGN or elsewhere in the brain where all streams of visual information are combined.
16. *b* is the answer. Axons from the nose synapse in the olfactory bulb, which makes connections to the amygdala and many other brain areas. The amygdala is involved in emotion, which may explain why some smells activate memories. (see Olfaction)
- a.* Olfaction does not relay signals through the thalamus.
- c.* Papillae are the structures containing taste buds; they are not activated by smells.
- d.* The basilar membrane is in the cochlea of the inner ear.
17. *d* is the answer. Papillae contain taste buds. (see Gustation)
- a.* Feeling a hot shower is the responsibility of the somatosensory system.
- b.* If green and red appear the same, one type of iodopsin, the photopigment in cones, may be missing.
- c.* Olfaction does not receive information from taste buds.
18. *d* is the answer. Pheromones are sexual chemical signals usually detected by the olfactory system. A cologne would fit this definition. (see Olfaction)
- a, c.* Both a tape of music and an alteration of voice concern hearing, not olfaction.
- b.* This describes an illegal date-rape drug. It has no relation to pheromones or olfaction.
19. *d* is the answer. Endorphins can reduce a person’s sense of pain. (see Pain)
- a, b.* Activated A-delta fibers indicate sharp pain; activated C fibers indicate dull aches.

- c. Naloxone is a drug that can block the pain-reducing effects of endorphins.
20. c is the answer. Proprioception, which includes kinesthesia and the vestibular sense, is the ability to know where the body parts are in space and in relation to each other. An acrobat would need excellent proprioception. (see Proprioception)
- a, b. A chef would need very discriminating taste buds, as would a wine taster.
- d. A musician would require an ability to discriminate sounds.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 2 that you answered correctly.

For each question you answered correctly, circle its number. (Quiz 1 numbers are not shaded; Quiz 2 numbers are shaded.) Are there patterns in the types of questions or the topics you got wrong that could direct your further study? Did you improve from Quiz 1 to Quiz 2?

CHAPTER 5

Perception

MULTIPLE-CHOICE QUESTIONS

SAMPLE QUIZ 1

1. A proponent of the computational view of perception would say,
 - a. "The environment has enough cues for our sensory systems to detect and perceive reality."
 - b. "Top-down processing is important in the perceptual process."
 - c. "Bottom-up processing is important in the perceptual process."
 - d. "Both (a) and (c) are true."
2. Vicki is sailing toward shore. Her expectation of seeing shore soon will _____ her response criterion for perceiving land.
 - a. increase
 - b. decrease
 - c. have no effect on
 - d. delay

3. Dante raises his hand each time he hears a tone over headphones in an experiment. The tone gets quieter and quieter until Dante misses hearing it half the time. After repeating the same procedure many times, the researcher concludes the experiment, because she has found Dante's
 - a. absolute threshold.
 - b. difference threshold.
 - c. internal noise.
 - d. response criterion.
4. Which of the following would *not* affect a person's sensitivity?
 - a. The level of internal noise in the nervous system
 - b. The person's motivation
 - c. The condition of the person's sensory system
 - d. The intensity of the stimulus
5. Subjects are watching a computer screen, which displays randomly appearing dots of different colors. Each time subjects see a red light, they are to press the "enter" key. When subjects are told they will be given \$1 each time they correctly indicate they've seen a red light, their number of _____ will increase.
 - a. thresholds
 - b. correct rejections
 - c. false alarms
 - d. misses
6. The experimenters in Question 5 used money to alter subjects'
 - a. difference threshold.
 - b. internal noise.
 - c. response criterion.
 - d. sensitivity.
7. Karen has purchased a tape that is supposed to contain subliminal messages to help her lose weight. According to research on subliminal self-help tapes, Karen's success in losing weight will most likely depend on
 - a. the content of the subliminal messages.
 - b. her expectation that the subliminal messages will help.
 - c. how relaxed the subliminal messages make her feel.
 - d. the number of times the subliminal messages occur.
8. What is the difference between just-noticeable differences (JNDs) and magnitude estimations?
 - a. The ability to detect a JND does not vary across senses. Magnitude estimation laws vary according to the specific senses being stimulated.
 - b. JND refers to the smallest detectable difference between stimuli. Magnitude estimation laws refer to specific amounts of difference between stimuli.
 - c. JND refers to specific amounts of difference between stimuli. Magnitude estimation laws refer to the smallest detectable difference between stimuli.
 - d. There is no difference. These terms are synonymous.
9. Four swimmers practicing their synchronized swimming routine are perceived as a group because they are performing the same movements at the same speed. This is an example of the grouping principle
 - a. closure.
 - b. common fate.
 - c. orientation.
 - d. interposition.
10. Harriet Greene is going to take her Brownie troop on a field trip to Chicago. She wants all the children to wear the same T-shirt. That way, a stray child will still be recognized as part of the troop. This demonstrates the principle of
 - a. similarity.
 - b. proximity.
 - c. orientation.

- d. textural gradients.
11. Knowing that an object is closer to you because it blocks out part of the background is called
 - a. linear perspective.
 - b. reduced clarity.
 - c. interposition.
 - d. motion parallax.
 12. A Cyclops has only one eye. What depth cue based on the properties of her visual system would a Cyclops *not* have?
 - a. Linear perspective
 - b. Motion parallax
 - c. Convergence
 - d. Reduced clarity
 13. As Cliff exits his front door using a garbage can lid as a shield, he sees a snowball coming straight for him. Although the size of the snowball on his retina is enlarging, he realizes the snowball is approaching, not getting larger, because of
 - a. induced motion.
 - b. looming.
 - c. motion parallax.
 - d. reduced clarity.
 14. When Jean sees her cat from one angle, she has no difficulty identifying her, but from another angle Jean isn't even sure that what she's seeing is a cat. Jean is having difficulty with
 - a. closure.
 - b. interposition.
 - c. proximity.
 - d. shape constancy.
 15. Bottom-up processing is congruent with the _____ approach to perception, and top-down processing is congruent with the _____ approach to processing.
 - a. computational; ecological
 - b. constructivist; computational
 - c. computational; constructivist
 - d. constructivist; ecological
 16. As soon as Jocelyn stepped on a tack, she reflexively pulled her foot up from its sharp point. Jocelyn primarily used _____ processing to sense and react reflexively.
 - a. bottom-up
 - b. parallel
 - c. serial
 - d. top-down
 17. Which of the following does *not* contribute to the creation of a perceptual set?
 - a. Context
 - b. Expectancy
 - c. Past experience
 - d. Sensitivity
 18. When Frieda first looked at an advertisement, she noticed only that it showed a glass of cola on a tray. After her friend Cal told her that he saw two people dancing in the blur on the left ice cube, Frieda instantly noticed the dancers. "You're right; I can see them," said Frieda, "but I think I see them mostly due to _____, since you made me expect them to be there."
 - a. bottom-up processing
 - b. top-down processing
 - c. common fate
 - d. similarity

19. As strings of letters were flashed on the screen, Carrie recognized the letter "t" more quickly in the word "met" than in the nonsense letter string "lgt." Carrie's brain was faster at recognizing the "t" in "met" because its features, "m," "e," and "t," have more connections due to Carrie's experience. _____ processing was most responsible for the differences in recognition speed.
- Bottom-up
 - Network
 - Relative
 - Serial
20. Ron needs to find the section of his physics text that lists general thermodynamics equations. Luckily he marked the top edge of the pages with a bright pink highlighter pen, so the important pages automatically grab his attention when he scans. Ron used _____ processing to locate the target pages.
- absolute threshold
 - network
 - parallel
 - schema

Total Correct (See answer key) _____

SAMPLE QUIZ 2

Use this quiz to reassess your learning after taking Quiz 1 and reviewing the chapter.

- The _____ viewpoint is best at explaining our use of the grouping principle, closure.
 - computational
 - constructivist
 - ecological
 - signal-detection
- Expecting to see a stimulus will _____ the response criterion.
 - increase
 - decrease
 - not influence
 - be influenced by
- Shari studies the factors that will affect whether a cheese lab technologist will notice white curd specks in a loaf of yellow processed cheese. Specifically, Shari needs to know how to decrease false alarms and increase hits; therefore, Shari should study
 - signal-detection theory.
 - subliminal stimuli.
 - optical acuity theory.
 - Weber's law.
- LaKisha has an ear infection that muffles the sounds presented to her during a signal-detection experiment. Because LaKisha's hearing is poor, she responds to very few of the tones. Her lowered _____ is causing an increase in _____.
 - absolute threshold; false alarms
 - difference threshold; misses
 - response criterion; false alarms
 - sensitivity; misses
- Your friend Jay suggests that to increase the sale of candy at your next charity film screening, you should insert the subliminal message "Eat more candy." throughout the film. Research in the area of subliminal messages suggests that you should tell Jay that the "Eat more candy" message most likely would
 - anger the audience.
 - be more effective than a regular advertising campaign.
 - have to appear more than once a minute to have an effect.
 - not lead to increased candy sales.

6. The just-noticeable difference depends on
 - a. extremes in the weakness or intensity of the stimulus.
 - b. the particular type of stimuli being compared.
 - c. genetic differences in a person's sensory system sensitivity.
 - d. how much of the stimulus there was to begin with, and which sense is being stimulated.
7. Jake is a detective. He is usually very good at his job but has been making mistakes lately. Last night, he was on a stakeout and let a suspect slip away. Which of the following explanations would point to inadequate sensitivity as the reason for Jake's mistake?
 - a. Jake was sure that the suspect was going to sleep that night instead of making a break for it.
 - b. Jake fell asleep in the car at about 5:00 a.m.
 - c. Jake knew that the suspect's partner was across the street aiming a gun at Jake. If Jake had made a move, he would have been shot.
 - d. Jake knows that he is going to retire soon; a few mistakes will not mar his record.
8. When you arrive at a party, you are distressed to discover that people have already paired off. Although couples are just talking while sitting near to each other, you think that no one is available to talk to. The perceptual grouping principle most likely causing your perception of the party attendees as several pairs of people rather than as individuals is
 - a. closure.
 - b. continuity.
 - c. figure-ground.
 - d. proximity.
9. A burglar will paint her face black and wear dark clothing in order to keep people from using which principle of perceptual organization or grouping?
 - a. Proximity
 - b. Figure-ground
 - c. Closure
 - d. Similarity
10. Stanley gazed down at his new grandson and saw the "spitting image" of his son, Hank. But when Edna first saw her grandson (the same baby), he looked just like her daughter at that age. This bias in perception exhibited by these proud grandparents demonstrates
 - a. top-down processing.
 - b. perceptual constancy.
 - c. feature detection.
 - d. the perception paradox.
11. A Persian cat bounds across the yard after a mouse, only to watch it crawl under the fence. The cat steps up to the fence and peers through a hole with one eye. He realizes that the mouse is already far away because it looks very small. This is an example of
 - a. convergence.
 - b. binocular disparity.
 - c. relative size.
 - d. looming.
12. Clint sculpts a figure of a penguin out of clay and photographs it. He makes a subtle change in the penguin's feet and photographs it again. Clint continues to subtly change and photograph the penguin until the figure has made a complete step. Clint develops the fifty photographs, puts them in order of occurrence, and flips through them. He perceives the penguin actually going through the movement of taking a step. This perceptual phenomenon is known as
 - a. motion parallax.
 - b. stroboscopic motion.
 - c. binocular disparity.
 - d. convergence.

13. _____ allow(s) us to perceive an object as being the same size despite a change in the size of the retinal image.
- Looming
 - Proximity
 - Size constancy
 - Motion parallax
14. After tying 100 yellow ribbons into bows for party decorations, Aparna saw blue afterimages. "I had no idea that would happen," says Aparna. "Therefore, my _____ processing must have been most active in creating the perception."
- bottom-up
 - constructivist
 - network
 - top-down
15. Which region of the brain has been identified by positron emission tomography (PET) scans as being the primary site where mental processing associated with attention takes place?
- Right hemisphere
 - Left hemisphere
 - Reticular formation
 - No single brain region has been identified as the attention center.
16. Which perceptual process is affected by expectations and motivation?
- Bottom-up processing
 - Internal noise
 - Top-down processing
 - Sensitivity
17. When Lou looks at a lily, her brain matches its features (stem, petals, fragrance, and color) to the perceptual category "flower." Such feature analysis is characteristic of _____ processing.
- bottom-up
 - ecological
 - illusory
 - top-down
18. Sasha is reading her textbook chapter while watching an engrossing program on television. Can Sasha devote attention to her book and the TV simultaneously?
- Yes, attentional resources are unlimited.
 - Yes, because each task is tapping into the same kind of attentional resource.
 - No, attentional resources are limited.
 - No, because each task is tapping into a different kind of attentional resource.
19. Although Alan appears to be listening as Rich talks about his new clothes, vacation plans, and exercise routine, Alan is thinking through his list of errands to run. Alan has
- covertly shifted attention.
 - overtly shifted attention.
 - used parallel distributed processing.
 - used serial processing.
20. Engineering psychologists used the outcome of perception research to suggest that the cursor on computer screens should blink to attract attention. The flashing light on the screen allows the operator to use _____ processing to locate the cursor.
- absolute threshold
 - network
 - parallel
 - serial

Total Correct (See answer key) _____

ANSWERS TO MULTIPLE-CHOICE QUESTIONS

Circle the question numbers you answered correctly.

Sample Quiz 1

1. *c* is the answer. Proponents of the computational view think that perception is the result of neurological and sensory system activity. (see Three Approaches to Perception)
 - a.* Someone with an ecological view would say this.
 - b.* Constructivists believe that we use top-down processing to construct our environment.
 - d.* Only *c* is correct.
2. *b* is the answer. Vicki's expectations of seeing a light on shore soon will decrease her response criterion. This means she will need less stimulus (light) to perceive that she is seeing a shore light. (see Signal Detection Theory)
 - a.* Increasing Vicki's response criterion means that she will be less likely to perceive a stimulus.
 - c.* *b* is the answer.
 - d.* The response criterion is the willingness or reluctance to respond to a stimulus; therefore, it is not something that can be delayed.
3. *a* is the answer. The absolute threshold is the point at which you perceive a stimulus half the time. (see Absolute Thresholds: Is Something Out There?)
 - b.* The difference threshold is the amount of change required before a person will just notice a difference in a stimulus.
 - c.* Internal noise is not something that can be seen or heard by a researcher, but it can interfere with a person's perception if it is too high. Internal noise is the automatic, random firing of cells in the nervous system.
 - d.* Expectancies and motivation affect our response criterion, which is our willingness or hesitancy to react to a stimulus.
4. *b* is the answer. Sensitivity is the ability to detect a stimulus. Motivation affects whether we do perceive a stimulus, but it does not affect our ability to perceive a stimulus. (see Signal Detection Theory)
 - a.* A very high level of internal noise may be mistaken for a very faint stimulus. This will alter sensitivity.
 - c.* The sensory system's physical health can affect its ability to perceive a stimulus. For example, a person with burned finger tips will be unable to detect slight pressure very well.
 - d.* The intensity of a stimulus will affect our ability to detect it. If the stimulus is below absolute threshold, it will be undetectable.
5. *c* is the answer. Because the participants have something to gain from seeing a stimulus, they are more likely to say they've seen one when it didn't actually appear. (see Signal Detection Theory)
 - a.* You may have been thinking of a change in the level of absolute or difference thresholds, but the number of these wouldn't change.
 - b.* The participants will not increase their number of correct rejections, because they are more motivated to see the light than not to see it.
 - d.* Misses will decrease, because participants are motivated by money to watch carefully.
6. *c* is the answer. The criterion was lowered by the chance to gain money. (see Signal Detection Theory)
 - a.* Difference thresholds are the smallest noticeable change in a stimulus and depend on the intensity of the stimulus, not factors in the subjects.
 - b.* Internal noise is the random firing of neurons and is not affected by motivation.
 - d.* Sensitivity is related to the abilities of the sensory systems and the amount of internal noise.

7. *b* is the answer. Research indicates that the placebo effect plays more of a role in whether subliminal messages work than the messages themselves. (see Thinking Critically: Can Subliminal Stimuli Influence Your Behavior?)
- a. d.* The content and number of subliminal messages will not influence a person as much as the person's belief in their effectiveness.
- c.* Relaxation is not a factor known to influence the effectiveness of subliminal messages.
8. *b* is the answer. Just-noticeable differences refer to detection of any difference, whereas magnitude estimation laws specify a difference or amount of change. (see Judging Differences: Has Anything Changed?)
- a.* One of the factors that affects detection of a JND is which sense is being stimulated. Magnitude estimation laws refer more to features of the stimuli being compared.
- c.* This is the reverse of the correct answer.
- d.* There is a difference.
9. *b* is the answer. Objects (or people) moving at the same rate and in the same direction are perceived as a group. (see Basic Processes in Perceptual Organization)
- a.* Closure would be filling in the gaps of a still object.
- c.* Orientation is one aspect of a stimulus that relates to texture, not movement.
- d.* Interposition is a depth perception cue.
10. *a* is the answer. Harriet Greene wants to be sure that all her Brownies look alike so that people will perceive them all as members of the same group. (see Basic Processes in Perceptual Organization)
- b.* If one child wanders away from the rest of the Brownies, she will *not* be close enough to be perceived as part of the group.
- c.* Even if one child strays from the group, she will still be in the same orientation (standing up) as everyone else in the museum. Her orientation will not distinguish her as one of Harriet Greene's Brownies.
- d.* Textural gradients are a depth cue, not a principle of grouping.
11. *c* is the answer. Interposition is a depth perception cue. (see Perception of Location and Distance)
- a.* Linear perspective is a depth cue. As parallel lines get farther and farther away, they seem to converge at a point.
- b.* Reduced clarity is a depth cue. As objects get very far away, we see them less clearly.
- d.* Motion parallax is a depth cue. As you move forward—for example, in a car—the objects that are close to you seem to go by more quickly than those that are far away.
12. *c* is the answer. The brain receives and processes information from the eye muscles about the amount of muscular activity. The eyes must converge, or rotate inward, to project the image of an object on each retina. The closer the object is, the greater the convergence is, and thus the greater is the muscular activity reported to the brain. The brain of a Cyclops would receive no information about the convergence since a Cyclops has only one eye. (see Perception of Location and Distance)
- a.* Linear perspective is a depth cue that can be seen with one eye.
- b.* Motion parallax is a depth cue that can be seen with one eye.
- d.* Reduced clarity is a depth cue that can be seen with one eye.
13. *b* is the answer. (see Perception of Motion)
- a.* Induced motion is not a term used in your text, but it is the feeling that we are moving when something on either side of us moves. For example, when sitting in a car in a parking lot, if both cars next to you back out, you may feel for a moment as if you are moving forward although your car is still.
- c.* Motion parallax is the difference in the *apparent* movement of objects, which occurs as we move by them.
- d.* Reduced clarity is the depth cue in which less clear images are perceived as farther away.

14. *d* is the answer. (see Perceptual Constancy)
 - a, b.* Both the grouping principle closure and the depth cue interposition would require that something was blocking Jean's view of the cat.
 - c.* Proximity is a grouping principle that automatically organizes objects that are close together into a group.
15. *c* is the answer. Both bottom-up processing and the computational approach rely on neural activity as the basis of perception. In bottom-up processing, neural cells analyze and recombine features of a stimulus to create the perceptual experience. The computational approach explains how manipulations within the nervous system transform sensory stimulation into perceptual experience. Both top-down processing and the constructivist approach suggest that expectations and inferences based on past experiences and prior knowledge strongly influence perception. (see Three Approaches to Perception)
 - a.* The computational approach would be congruent with bottom-up processing. However, the ecological approach discounts inferences and expectations and suggests that information supplied by the environment is primary in our perception of the world.
 - b.* This is the reverse of the correct answer.
 - d.* The computational approach and bottom-up processing rely on neural activity as the basis of perception. The constructivist approach and top-down processing are concerned with interpretation of stimuli. The ecological approach considers the environment to be key in perception.
16. *a* is the answer. Bottom-up processing is the reaction of cells in the nervous system to aspects of a stimulus. The cells each process one characteristic, and eventually the characteristics are combined to make a whole stimulus perception. In a reflexive action, sensory neurons send the pain information to the spinal cord, which sends a "pull away" message to the muscles. (see Bottom-Up Processing)
 - b, c.* Parallel and serial processing are used when a person is scanning the environment for a stimulus.
 - d.* Top-down processing is influenced by motivation and expectation.
17. *d* is the answer. A perceptual set is a readiness to perceive a stimulus in a certain way. Sensitivity is the ability to perceive an object *at all*, not an indication of *how* we perceive it. (see Top-Down Processing)
 - a.* Context can change the way we perceive an object. For example, the sound of "reed" means two different things depending on the context of the sentence. "The oboe contains a reed." "I like to read."
 - b.* Our expectations, based on past experience and context, can create a perceptual set.
 - c.* Our past experiences can create perceptual sets. A person who does not have children may take some time to realize that children's bloodcurdling screams may not always signify pain. Anyone who has been around children for any length of time knows that they sometimes scream while they play and that alarm is not always the necessary response.
18. *b* is the answer. Frieda's bottom-up processing sent on information about the features of the objects in the advertisement, but it was Cal's suggestion that caused her to see the dancers. (see Top-Down Processing)
 - a.* The expectation of what was in the picture influenced the perception. Frieda *did* use bottom-up processing, but it doesn't explain the difference between her two impressions.
 - c.* Common fate is the grouping principle that uses similar movement to place objects into a group.
 - d.* Similarity is the grouping principle that states that the more resemblance there is between items, the more likely they will be grouped.
19. *b* is the answer. Network processing causes the word superiority effect that Carrie experienced. The neural links between letters previously seen together in a word are stronger than those between letters not previously shown together as a word. (see Network Processing)
 - a.* Perception cannot occur without bottom-up processing, the reaction of nervous system cells to features of the stimulus, but the effect Carrie experienced was related to the networks of information in Carrie's brain.
 - c.* Relative is not a processing type.
 - d.* Serial processing is when a person must scan the environment carefully, examining several characteristics before deciding if the target has been found.

20. *c* is the answer. When a person can quickly and automatically pick out a target by examining all locations at once, it is parallel processing. Ron can examine the whole edge of the book to rapidly locate the highlighted page edges. (see Attention and the Brain)
- a.* Absolute threshold deals with sensing the presence of a stimulus, not finding a specific object from among an array of stimuli.
 - b.* Network processing emphasizes the links between features of objects, meanings, and so on.
 - d.* Schemas are mental representations created based on experience and are used in top-down processing, but an actual visual marker was used in this example.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 1 that you answered correctly.

ANSWERS TO MULTIPLE-CHOICE QUESTIONS

Circle the question numbers you answered correctly.

Sample Quiz 2

1. *b* is the answer. The constructivist viewpoint is that we piece together a perception from fragmented parts of sensory information by using our experience and knowledge. In closure, missing gaps are filled in to create a perception of a whole, based on our experience of how the whole perception should appear. (see Three Approaches to Perception)
 - a.* A computational view is one that explains that features of the environment are formed into complete perceptions through the actions of nervous system structures and mechanisms.
 - c.* The ecological view asserts that everything needed for perception is present in the environment; we only have to attend to the important aspects.
 - d.* Signal-detection theory does not address why someone would use the grouping principle of closure.
2. *b* is the answer. Response criterion determines the amount of physical energy needed for a person to justify reporting that a stimulus is present. Expecting to see a stimulus decreases, or lowers, the response criterion. (see Signal Detection Theory)
 - a.* Expecting to see the stimulus does not increase, or raise, the response criterion. In other words, when the response criterion is decreased, we are more likely to report seeing a stimulus because we know it is coming.
 - c, d.* Expectations do influence the response criterion, and the response criterion does not influence expectations.
3. *a* is the answer. Signal-detection theory addresses the factors that influence whether we will perceive a stimulus. (see Signal Detection Theory)
 - b.* By definition, subliminal stimuli are *not* detectable. Here, Shari is concerned with the technologist's response criterion for detectable specks of cheese—part of signal detection theory.
 - c.* Optical acuity theory is not a term.
 - d.* Weber's law addresses the perception of differences between stimuli, not stimulus detection itself.
4. *d* is the answer. An ear infection muffling sounds has affected the capacity of LaKisha's sensory systems, one influence on sensitivity. LaKisha doesn't hear many of the tones, or, in other words, she misses them. (see Signal Detection Theory)
 - a.* Absolute threshold is the point at which a stimulus is perceived on half of its presentations; false alarms are saying stimuli were presented when they weren't.
 - b.* The experiment is not testing whether LaKisha can notice a difference between two stimuli, and her difference threshold is not affected.
 - c.* Nothing is said about LaKisha's response criterion; therefore, we don't know if she lowered it; she did not have any false alarms since she was barely responding to any tones.
5. *d* is the answer. Subliminal perception does not control behavior. (see Thinking Critically: Can Subliminal Stimuli Influence Your Behavior?)
 - a.* No evidence suggests that subliminal messages will anger people.
 - b.* Regular advertising campaigns that are consciously perceived are more influential than subliminal messages.
 - c.* Presenting subliminal messages more than once a minute still will not cause people to buy candy.

6. *d* is the correct answer. These are the two factors that determine the ability to detect a difference in the amount of stimulation received. (see Judging Differences: Has Anything Changed?)
 - a.* Extremes in stimuli are handled by the magnitude estimation laws, not by Weber's law.
 - b.* Particular types of stimuli are covered by magnitude estimation laws
 - c.* Individual differences are addressed in signal-detection theory, not by the general formula for just-noticeable differences in Weber's law.
7. *b* is the answer. Changes in internal noise, stimulus intensity, or the workings of the sensory system alter sensitivity. If Jake is asleep, his visual sensory system is not working. Jake's eyes must be open before he can see the suspect creep by the car. (see Signal Detection Theory)
 - a.* If Jake thought that the suspect was in for the night, then his expectations of activity would decrease. This would increase the necessary response criterion but would not affect sensitivity.
 - c.* If Jake thought that the suspect's partner was aiming a gun at him, then his motivation to grab the suspect might have been lowered. Jake may think he is too close to retirement to take chances. This would affect Jake's motivation, not his sensitivity.
 - d.* If Jake is not concerned about his record, he may not be as attentive at work. This would lower his response criterion (he is probably a bit reluctant to hear the suspect) and increase his absolute threshold (the amount of noise required before Jake hears the suspect).
8. *d* is the answer. The people closer to each other are seen as groups. (see Basic Processes in Perceptual Organization)
 - a.* The grouping principle closure fills in gaps.
 - b.* Continuity groups seemingly unbroken forms.
 - c.* Figure-ground would assign some figures to the foreground and others to the background, but it would not account for your perception of pairs of people at the party.
9. *b* is the answer. Burglars want to fade into the background. Painting their faces black and wearing dark clothing make it very difficult to see the burglars as separate from the background of the dark sky. (see Basic Processes in Perceptual Organization)
 - a.* Proximity is the tendency to perceive objects that are close together as part of a group.
 - c.* Closure is the ability to fill in the gaps when sensory stimulation is missing. The black paint and dark clothing do not cause a lack of stimuli but do affect our ability to distinguish background and foreground.
 - d.* Things that are similar are perceived as part of the same group. This question deals with just one burglar, not groups of burglars.
10. *a* is the answer. Top-down processing is guided by expectations and motivations. Stanley, the proud grandparent, expected to see the features of his side of the family, and Edna, equally proud, expected to see the features of her side of the family. (see Top-Down Processing)
 - b.* Perceptual constancy is the perception of objects as constant in size, shape, and color, despite changes in their retinal image. It does not explain the difference between Stanley's and Edna's perceptions.
 - c.* Feature detection refers to the activity of particular cells in the cortex corresponding to particular features of stimuli in the environment.
 - d.* The perception paradox refers to the idea that because the perceptual system functions efficiently and effectively, it is a very complex system and thus difficult to study.
11. *c* is the answer. Although several of the alternatives are depth cues, the reduced or relative size of the mouse tells the cat that his quarry is far away. (see Perception of Location and Distance)
 - a.* Convergence is a depth cue, but it requires a visual image from both eyes. The cat is peering through the fence with only one eye.
 - b.* Binocular disparity is a depth cue, but it requires a visual image from both eyes. The cat is peering through the fence with only one eye.
 - d.* Looming is a motion cue. Objects are perceived as moving closer as they take up more and more of our retinal space.

12. *b* is the answer. Stroboscopic motion, a motion illusion, enables us to interpret motion from a series of still images flashed in rapid succession. (see Perception of Motion)
 - a.* Motion parallax is a visual depth cue in which near objects seem to move faster across the visual field than objects in the distance.
 - c.* Binocular disparity provides information about the distance of objects. It is the difference between the two retinal images of an object.
 - d.* Convergence is another depth cue. The more eyes converge inward, the closer the object.
13. *c* is the answer. Due to size constancy, we perceive objects as retaining their same size despite changes in retinal size. (see Perceptual Constancy)
 - a.* Looming is a motion cue. Objects fill the entire retinal space as they get closer and are perceived as moving.
 - b.* Proximity is a grouping principle. The closer objects are, the more likely we are to perceive them as part of the same group.
 - d.* Motion parallax helps us perceive depth.
14. *a* is the answer. Aparna's sensory systems automatically reacted to create the afterimages. (see Bottom-Up Processing)
 - b.* Constructivist is a view, not a processing type.
 - c.* Network processing involves accessing linked concepts.
 - d.* Top-down and bottom-up processing generally work together, but top-down processing is affected by expectation and motivation—neither of which was a factor in the creation of the afterimages.
15. *d* is the answer. Particular patterns of blood flow have been observed in different areas of the brain, depending on the type of attentional process that was active. (see Attention and the Brain)
 - a, b, c.* No single brain region has been identified as the attention center.
16. *c* is the answer. (see Top-Down Processing)
 - a.* The contribution of our sensory systems to the process of perception is called bottom-up processing. For example, lateral inhibition causes us to see edges and contrasts quite clearly. Our expectations and motivation do not alter lateral inhibition.
 - b.* Internal noise is the spontaneous, random firing of neurons and is unaffected by expectations and motivation.
 - d.* Sensitivity is influenced by internal noise, stimulus intensity, and the health of the sensory systems, not by expectations or motivation.
17. *a* is the answer. Feature analysis is part of bottom-up processing. It is usually followed by top-down processing, but that is not described in the item. (see Bottom-Up Processing)
 - b.* There is no such thing as ecological processing; you may have been thinking of the ecological view of perception.
 - c.* Illusory processing is a made-up term.
 - d.* Top-down processing and bottom-up processing work together. Lou's top-down processing probably started as soon as the perceptual category "flower" was activated, but her inference that, for example, the flower was given to her by someone who likes her is not described in the question.
18. *c* is the answer. Attentional resources are limited, particularly when tasks involve the same type of attentional resources. This would be applicable in Sasha's case because both reading and following the TV program involve perceiving incoming stimuli. (see Attention)
 - a, b, d.* Attentional resources are *not* unlimited. If the same resource is being tapped by two different tasks, as is the case here, only one task can be performed. If two different attentional resources are being tapped, it might be possible to perform them simultaneously.
19. *a* is the answer. Covert orienting is a shift of attention that isn't possible for the casual observer to see. (see Attention)
 - b.* An overt attention shift would be turning away from Rich to stare at an approaching person.
 - c, d.* Parallel and serial processing are types of searches.

20. *c* is the answer. Parallel processing is observing all locations at once in a search. It is possible when the target stands out from the background. (see Attention and the Brain)
- a.* Absolute threshold is the point at which you can perceive an object 50 percent of the time; it is not a type of processing.
 - b.* Network processing deals more with links between stimuli than it does with searching for a target.
 - d.* Serial processing is necessary when people must examine more than one feature of an object before deciding if it is the target. It requires a slower, more careful search.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 2 that you answered correctly.

For each question you answered correctly, circle its number. (Quiz 1 numbers are not shaded; Quiz 2 numbers are shaded.) Are there patterns in the types of questions or the topics you got wrong that could direct your further study? Did you improve from Quiz 1 to Quiz 2?

CHAPTER 6

Learning

MULTIPLE-CHOICE QUESTIONS

Sample Quiz 1

1. In classical conditioning, an organism learns
 - a. an association between the unconditioned stimulus and the conditioned response.
 - b. that the conditioned stimulus is a substitute for the unconditioned stimulus.
 - c. that the conditioned stimulus predicts the occurrence of the unconditioned stimulus.
 - d. an association between the unconditioned response and the conditioned response.
2. Spontaneous recovery follows
 - a. reconditioning.
 - b. extinction.
 - c. stimulus control.
 - d. stimulus degradation.
3. Which of the following demonstrates the need for an adaptive balance between stimulus discrimination and stimulus generalization?
 - a. Phobias
 - b. Learned helplessness

- c. Extinction
 - d. All of the above
4. Reconditioning refers to
- a. the appearance of a conditioned response following extinction.
 - b. the elimination of the association between the conditioned stimulus and the unconditioned stimulus.
 - c. the occurrence of spontaneous recovery.
 - d. relearning the connection between the conditioned stimulus and the unconditioned stimulus after extinction.
5. Marsha reads aloud a list of words and shoots a puff of air at Kat's eye. It's only after Marsha says "nice" that she blasts Kat's eye with air to make her wink. Eventually Kat winks even when Marsha says "nice" and doesn't shoot the puff of air into her eye. If Kat undergoes extinction, she will
- a. be unable to wink at anything.
 - b. feel she is being punished.
 - c. wink when she hears the word "night."
 - d. not wink when she hears the word "nice."
6. The fact that you didn't notice the feeling of your underwear until you read this sentence is an example of
- a. habituation.
 - b. hypothalamic stimulation.
 - c. stimulus discrimination.
 - d. spontaneous recovery.
7. The idea behind the disequilibrium hypothesis is best explained by which of the following old sayings?
- a. Beauty is in the eye of the beholder.
 - b. Absence makes the heart grow fonder.
 - c. Birds of a feather flock together.
 - d. Too many cooks spoil the broth.
8. Manuel has learned that every time he cleans his room, his mother makes his favorite dessert. This is an example of
- a. classical conditioning.
 - b. negative reinforcement.
 - c. operant conditioning.
 - d. association of stimuli.
9. In operant conditioning, negative reinforcers are
- a. pleasant stimuli presented following a response.
 - b. unpleasant stimuli that are removed following a response.
 - c. methods of decreasing a response.
 - d. rewards considered basic to survival, such as food and drink.
10. Ten minutes before a movie starts, the theater is filled with people who are talking or laughing. As soon as the lights go out, everyone becomes quiet. A few people, who continue to laugh out loud and prevent the audience from hearing the show, are booed and hissed until they are quiet. Turning off the lights serves as a _____ in this example of operant conditioning.
- a. positive reinforcer
 - b. negative reinforcer
 - c. punishment
 - d. discriminative stimulus
11. Sometimes Amy hits her sister, Zoe, in the arm until Zoe says "I give," and then Amy stops. Because Amy stops hurting Zoe when she says "I give," Zoe says it whenever she is being hit. In this example of _____, the operant is _____.
- a. negative reinforcement; Zoe saying "I give"
 - b. positive reinforcement; Amy stops hitting Zoe
 - c. punishment; Zoe saying "I give"

- d. punishment; Amy stops hitting Zoe
12. In operant conditioning, if a reinforcer is on a fixed-ratio schedule it is presented after a(n)
- fixed amount of time.
 - fixed number of responses.
 - average number of responses.
 - average amount of time.
13. Which reinforcement schedule produces the fastest extinction rate?
- Fixed ratio
 - Primary
 - Variable ratio
 - Variable interval
14. Every fifth time Russell washes the dishes, his mom gives him a candy bar, and he now washes them every day. Susan's dad gives her reinforcement for washing the dishes every Friday, and she also washes them every day. What schedules of reinforcement are Russell and Susan on, respectively?
- Fixed interval, variable interval
 - Fixed ratio, fixed interval
 - Variable ratio, fixed interval
 - Variable interval, fixed ratio
15. Julio and Carlos's mother asks them what they want for breakfast. Carlos replies, "I want some damn corn flakes." His mother immediately yells, "Don't say that!" and repeats the question. Carlos replies, "Well okay. I'll have some damn rice puffs." Carlos's mother becomes angry and sends Carlos to his room. She then looks at Julio and says, "What do you want for breakfast?" Julio replies, "I don't know, but you can be sure I don't want any damn cereal." Julio's response illustrates
- the effectiveness of negative reinforcers.
 - stimulus discrimination.
 - the disadvantages of using punishment.
 - habituation.
16. In learned helplessness, an organism believes that
- behavior is unrelated to consequences.
 - certain behaviors always result in negative consequences.
 - positive consequences are rare.
 - certain behaviors provide escape from negative stimuli.
17. Gertrude's grandfather came to visit her recently for the first time. In the middle of the night he got up to use the bathroom. Half asleep, he took a wrong turn and walked into a wall. This is an example of
- use of an incorrect cognitive map.
 - reverse insight.
 - latent learning.
 - vicarious learning.
18. After being bitten by a dog at a young age, Cathy became fearful of all types of dogs. When Cathy sees a dog, her heart races and she feels like running away. From the list below, which is the conditioned stimulus (CS) for Cathy?
- Dog bite
 - Fear
 - Running away
 - Seeing a dog
19. Later Cathy watches a number of people petting and playing with a dog and decides that dogs aren't just scary and mean. The next day at her neighbor's house she pets their dog. She has learned to pet a dog through
- classical conditioning.
 - operant conditioning.
 - vicarious conditioning.
 - observational learning.

20. Kelly watched her older brother pick up fallen apples in their backyard and then receive praise from their parents. The next time apples fell down, Kelly went outside to pick them up. What kind of conditioning best explains Kelly's learning of this new behavior?
- Classical conditioning
 - Vicarious conditioning
 - Operant conditioning
 - Instrumental conditioning

Total Correct (See answer key) _____

Sample Quiz 2

Use this quiz to reassess your learning after taking Quiz 1 and reviewing the chapter.

- In classical conditioning, a neutral stimulus
 - is one that initially does not elicit a response.
 - is synonymous with an unconditioned stimulus.
 - causes an unconditioned response.
 - predicts the presence of an unconditioned response.
- Letitia's first experience at the dentist was a traumatic one. During that first visit, the dentist used no anesthetic before drilling her teeth. Now, just sitting in the waiting room and hearing the whirring sound of the drill make Letitia nauseated. This is an example of what kind of conditioning?
 - Classical conditioning
 - Negative reinforcement
 - Operant conditioning
 - Positive reinforcement
- When Antonio rode the Ferris wheel at the amusement park for the first time, he became very dizzy. Now when Antonio sees an advertisement for amusement parks, he feels nauseated. In this case, the unconditioned stimulus is
 - the Ferris wheel ride.
 - the feeling of dizziness.
 - nausea.
 - the sight of an amusement park.
- In this case of Antonio's feelings about Ferris wheels, the conditioned response is
 - dizziness.
 - the Ferris wheel ride.
 - the sight of an amusement park.
 - nausea.
- In the case of Antonio's feelings about Ferris wheels, the conditioned stimulus is
 - dizziness.
 - the Ferris wheel ride.
 - the sight of an amusement park.
 - nausea.
- Stimulus generalization involves responding to stimuli that
 - had always occurred in the presence of the unconditioned stimulus.
 - produce a reflexive response.
 - are similar but not identical to the conditioned stimulus.
 - are similar to the unconditioned stimulus but do not produce an unconditioned response.
- In September, Jefferson High School's fire alarm sounded, and students ran from the building to escape the flames. For the next few weeks, the school experienced a rash of false alarms, and people began to ignore the sound. The alarms were repaired and did not sound for the next few months. Then in December, a fire alarm sounded, and students ran from the building in panic. What phenomenon was responsible for the students' renewed fear?
 - Reconditioning
 - Spontaneous recovery

- c. Stimulus control
 - d. Stimulus generalization
8. After a lab rat was exposed to repeated pairings of a dark blue light and electrical shock, he became very nervous whenever a turquoise light was flashed in his cage. This phenomenon is called stimulus
- a. generalization.
 - b. discrimination.
 - c. degradation.
 - d. control.
9. Which of the following types of conditioning produces the strongest conditioned response?
- a. Spontaneous conditioning
 - b. Forward conditioning
 - c. Simultaneous conditioning
 - d. Backward conditioning
10. When Tanya was given chemotherapy, she developed a conditioned response to the food that she ate just prior to feeling nauseated. Tanya developed an aversion to the food rather than to the song she heard on the radio due to
- a. biopreparedness.
 - b. generalization.
 - c. simultaneous conditioning.
 - d. signal strength.
11. In operant conditioning, discriminative stimuli
- a. automatically trigger a conditioned response.
 - b. indicate the presence of reinforcement if a response is made.
 - c. are successive approximations of a desired response.
 - d. are similar but not identical to the conditioned stimulus.
12. Punishment is
- a. the presentation of an aversive stimulus.
 - b. the removal of a pleasant stimulus.
 - c. a means to decrease the occurrence of an undesired response.
 - d. all of the above.
13. Kent does not like to take drugs of any kind. When he goes to the dentist, he tries not to ask for any anesthesia. However, sometimes he cannot handle the pain of drilling, and so he lets the doctor give him a shot. This illustrates the use of
- a. a positive reinforcer.
 - b. a negative reinforcer.
 - c. punishment.
 - d. learned helplessness.
14. Anne is angry at her boss and would like to tell him exactly how she feels about him. But the last time Anne did something similar, she was fired. So, in order not to lose her job, Anne keeps her temper under control. What kind of learning does this represent?
- a. Escape conditioning
 - b. Classical conditioning
 - c. Avoidance conditioning
 - d. Discriminative stimuli
15. Shaping is used when the conditioned response
- a. is physically difficult to perform.
 - b. is to be decreased.
 - c. has never been displayed before.
 - d. is reflexive.
16. Which reinforcement schedule produces the highest response rate?
- a. Fixed ratio

- b. Fixed interval
 - c. Variable ratio
 - d. Variable interval
17. Two patients are recovering from surgery. Patient A is given an injection every six hours. Patient B is hooked up to a machine that delivers pain medication whenever he presses a button. Who is on a continuous reinforcement schedule?
- a. Patient A
 - b. Patient B
 - c. Both of them
 - d. Neither of them
18. Advertisements for breath mints frequently involve a chance meeting of strangers who end up falling in love because they had great breath when they met. Advertisers are hoping that people who watch the commercial will learn by _____ that using breath mints will improve their love lives.
- a. vicarious conditioning
 - b. observation
 - c. classical conditioning
 - d. stimulus control
19. Which type of practice leads to better retention of material studied?
- a. No practice
 - b. Massed practice
 - c. Distributed practice
 - d. Any type of practice
20. All else being equal, who will develop the most expertise in their skill?
- a. Danny, who buys a "Learn Critical Thinking in Your Sleep" tape.
 - b. Emily, who received constant coaching while practicing her tennis serves.
 - c. John, who gets detailed feedback during every wrestling move he makes.
 - d. Pamela, who independently practices her violin every day.

Total Correct (See answer key) _____

ANSWERS TO MULTIPLE-CHOICE QUESTIONS

Circle the question numbers you answered correctly.

Sample Quiz 1

1. *c* is the answer. The conditioned stimulus predicts the occurrence of the unconditioned stimulus. (see Pavlov's Discovery)
 - a.* There is no relationship between the UCS and the CR. The UCS causes a natural reflexive response (UCR); only the conditioned (learned) stimulus causes a conditioned (learned) response.
 - b.* If the CS was merely a substitute for the UCS, the conditioned response would always be identical to the unconditioned response (UCR). This is not the case.
 - d.* No relationship between the UCR and the CR is learned.
2. *b* is the answer. For a conditioned response to recover, it must first have undergone extinction. (see Conditioned Responses Over Time: Extinction and Spontaneous Recovery)
 - a.* Reconditioning once again pairs the conditioned stimulus and the unconditioned stimulus. The conditioned response is relearned. Spontaneous recovery is just that, spontaneous. No relearning is necessary.
 - c.* Stimulus control is associated with operant conditioning. Spontaneous recovery is a phenomenon in classical conditioning.
 - d.* There is no learning phenomenon called stimulus degradation.
3. *a* is the answer. Some phobias are learned after generalizing the conditioned stimulus in a classical conditioning scenario. For example, after one bad experience with a dog (CS = sight of dog, UCS = dog bite, UCR = pain, CR = fear and escape), a child may learn to fear all real dogs or even pictures of dogs. Although being able to generalize the conditioned stimulus is an adaptive response because the child will be wary of dogs, he or she should also be able to discriminate between large, menacing dogs that could really cause injury and a picture of a dog. (see Stimulus Generalization and Discrimination)
 - b.* In operant conditioning, stimulus discrimination and generalization indicate that a reinforcement is available if the organism responds. In learned helplessness, an organism learns that no response it makes will bring about a reinforcement.
 - c.* Extinction is a deterioration of the relationship between the CS and the UCS (classical conditioning) or between a response and a reinforcing or punishing stimulus (operant conditioning). Stimulus generalization and discrimination require learned relationships to be intact; an organism won't respond at all if a stimulus no longer signals an important event or reward.
 - d.* *a* is the answer.
4. *d* is the answer. Reconditioning is a repetition of the conditioning process. This occurs after extinction; if extinction had not already occurred, there would be no need for reconditioning. (see Conditioned Responses Over Time: Extinction and Spontaneous Recovery)
 - a, c.* The occurrence of a conditioned response after extinction is called spontaneous recovery.

- b.* The process of extinction removes the association between the CS and the UCS so that the CS no longer predicts the presence of the UCS. Reconditioning restores the association between the CS and the UCS.
5. *d* is the answer. A person's conditioned response is extinguished when a long time passes without the unconditioned stimulus appearing with the conditioned stimulus. (see Conditioned Responses Over Time: Extinction and Spontaneous Recovery)
- a.* Kat will be able to wink at things if she undergoes extinction. She will just be less likely to wink at "nice" than she was before.
- b.* A feeling of being punished wouldn't happen as a result of discontinuing the pairing of the CS and UCS.
- c.* Winking upon hearing the word "night" is an example of generalization.
6. *a* is the answer. In habituation, an organism stops responding to repeated stimuli that do not signal a change in the environment. When you put your underwear on in the morning, you feel it. However, after a few minutes, your body begins to ignore the sensation (see Learning About Stimuli)
- b.* Hypothalamic stimulation has nothing to do with habituation.
- c.* In classical conditioning, organisms discriminate among stimuli when they can make finer and finer distinctions among them. For example, if the CS is a red ball, an organism may not respond to a green ball. Stimulus discrimination doesn't play a role in the process of habituation.
- d.* Spontaneous recovery occurs when a CS that has not been paired with a UCS for some time elicits a conditioned response.
7. *b* is the answer. This old saying suggests that if two people are kept apart, their feelings for each other will become stronger. This is very similar to the disequilibrium hypothesis which asserts that if we are kept from performing an activity, that activity will become more desirable and may serve as a reinforcer. (see Why Reinforcers Work)
- a.* This saying, that each of us constructs our own idea of what is beautiful, is more congruent with top-down perceptual processing, which was discussed in the last chapter.
- c.* That we are attached to those who are like us is an idea that would apply more to interpersonal attraction, which will be discussed in Chapter 17.
- d.* This idea suggests that tasks are best completed individually or in a group with only one leader giving directions.
8. *c* is the answer. Operant conditioning involves learning that behaviors have consequences. When Manuel cleans his room (the operant), his mom makes his favorite dessert (the consequence). (see From the Puzzle Box to the Skinner Box)
- a, d.* Classical conditioning involves making an association between stimuli such that one (CS) comes to predict the presence of the other (UCS). This example involves learning that a behavior (cleaning the room) will bring about a reinforcer (dessert) and is therefore an example of operant conditioning.
- b.* A negative reinforcer is an unpleasant stimulus that is removed following a desired response. In this case, a positive reinforcer (a pleasant stimulus: dessert) is being presented following a desired behavior (cleaning the room).
9. *b* is the answer. In operant conditioning, reinforcers always produce a positive effect and work to increase a behavior. A negative reinforcer is a negative stimulus that is removed after the organism displays a desired response. (see Basic Components of Operant Conditioning)
- a.* Positive reinforcers are pleasant stimuli that are presented after an organism displays a desired response.
- c.* Punishment and extinction are used to decrease the occurrence of a response. (You may be confusing punishment and negative reinforcers.) Remember, reinforcements (both positive and negative) increase the occurrence of a desired behavior.
- d.* Rewards that are basic to survival are primary reinforcements.

10. *d* is the answer. A discriminative stimulus tells the people in the theater that if they are quiet (the response), they will be rewarded by seeing a movie (the reinforcement). Those who do not pay attention to the light (those who are not under the control of the light stimulus) are punished by being booed and hissed at. (see Basic Components of Operant Conditioning)
 - a.* The lights are not turned off to reward the audience for its behavior.
 - b.* The turned-off lights do not represent the removal of an unpleasant stimulus following the display of a desired behavior. Lights that are on are not unpleasant, and the audience did not display any behaviors in order to get the lights to go out.
 - c.* Turning off the lights does cause a decrease in the behavior that preceded it, but turned-off lights are not aversive, so they cannot be considered punishment.
11. *a* is the answer. Zoe is being negatively reinforced for saying "I give." When she says it, Amy removes the unpleasant stimulus (hitting her arm). (see Basic Components of Operant Conditioning)
 - b.* Amy is not rewarded for stopping her hitting.
 - c.* If Zoe were punished for saying "I give," she would be less likely to say it in the future.
 - d.* If Amy were punished for stopping her hitting, she would be less likely to stop hitting in the future.
12. *b* is the answer. (see Forming and Strengthening Operant Behavior)
 - a.* This is called a fixed-interval schedule.
 - c.* This is called a variable-ratio schedule.
 - d.* This is called a variable-interval schedule.
13. *a* is the answer. A fixed-ratio schedule of reinforcement produces the fastest rate of extinction because the organism realizes very quickly that reinforcements have ceased to be presented and that after the appropriate number of responses has been made, the reinforcement should be there. A continuous schedule of reinforcement, which is a type of fixed-ratio schedule, produces the fastest rate of extinction possible. (see Forming and Strengthening Operant Behavior)
 - b.* There is no such thing as a primary reinforcement schedule. Primary reinforcers are events or stimuli that are inherently rewarding, like treats for animals.
 - c, d.* Organisms on a variable schedule of reinforcement cannot predict when the reinforcement will appear. They therefore take longer to realize that the reinforcement is missing once the extinction process has begun.
14. *b* is the answer. A fixed number of behaviors must be exhibited by Russell to receive reinforcement. Susan must wait a fixed amount of time before receiving reinforcement for her actions. (see Forming and Strengthening Operant Behavior)
 - a.* Russell doesn't have to wait a set amount of time before reinforcement. If he washed dishes twice a day while company was around he could have his reinforcement (after five operants) in a day and a half. If he skipped a day of washing dishes, he would still get rewarded after the fifth operant, but it might take six days. Susan does not have to wait differing amounts of time; she is reinforced every Friday.
 - c, d.* Russell is on a fixed-ratio schedule and Susan is on a fixed-interval schedule.
15. *c* is the answer. Sometimes humans or animals do not understand what it is they are being punished for; this is one of the disadvantages of using punishment. Julio thought his mother was angry because Carlos wanted cereal, not because Carlos used a swear word. (see Punishment)
 - a.* Negative reinforcers are the removal of negative stimuli following a desired behavior. The boy's mother did not remove a negative stimuli; she added one by yelling and sending Carlos to his room.
 - b.* Stimulus discrimination is found in classical conditioning scenarios. This is an example of operant conditioning.
 - d.* In habituation, organisms stop paying attention to repetitive stimuli. Everyone is paying attention here.

16. *a* is the answer. In learned helplessness, an organism learns that its behaviors are unrelated to the consequences that occur. It learns that it is helpless or unable to control its circumstances. (see Learned Helplessness)
 - b.* If an organism learns that certain behaviors always result in negative consequences, then it is not helpless; it can avoid doing those behaviors.
 - c.* Learning that positive consequences are rare is not learned helplessness. In learned helplessness an organism learns that its behaviors are unrelated to the consequences that occur.
 - d.* In learned helplessness an organism learns the opposite: that no behavior provides escape from negative stimuli or consequences.
17. *a* is the answer. Gertrude's grandfather used a cognitive map of his own house when he sleepily tried to find his way to the bathroom in hers. (see Latent Learning and Cognitive Maps)
 - b.* There is no such thing as reverse insight.
 - c.* Latent learning occurs when an organism learns something but does not overtly demonstrate this new knowledge until later. If Gertrude's grandfather had successfully learned a cognitive map and made it to the bathroom without walking into a wall, this would have been an example of latent learning.
 - d.* To learn a response vicariously, an organism must watch someone else display that response and be rewarded or punished for it.
18. *d* is the answer. Seeing a dog is enough to make Cathy fearful. (see Pavlov's Discovery)
 - a.* The unconditioned stimulus is the dog bite.
 - b, c.* These are the likely conditioned responses.
19. *d* is the answer. Cathy watched others petting a dog and learned from it. (see Observational Learning: Learning by Imitation)
 - a.* Classical conditioning is the pairing of unconditioned stimuli with neutral stimuli.
 - b.* In operant conditioning a person's behavior is followed by a consequence. According to the story, Cathy only watched people; she wasn't rewarded.
 - c.* Vicarious conditioning is a type of observational learning in which a person sees someone reinforced or punished for his or her actions and learns to behave accordingly. This scenario says nothing about consequences of actions of petting.
20. *b* is the correct answer. In vicarious conditioning, through observation, Kelly learns that picking up apples results in pleasant circumstances—praise; as a result, at the next opportunity, she performs the behavior. (see Observational Learning: Learning by Imitation)
 - a.* Classical conditioning is the learning of a connection between a neutral stimulus and a stimulus that automatically leads to a response.
 - c.* Operant conditioning is first-hand learning of the consequences of behaviors. A behavior that results in favorable consequences is likely to be repeated in the future.
 - d.* Instrumental conditioning is another term for operant conditioning.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 1 that you answered correctly.

ANSWERS TO MULTIPLE-CHOICE QUESTIONS

Circle the question numbers you answered correctly.

Sample Quiz 2

1. *a* is the answer. A neutral stimulus becomes a conditioned stimulus (CS) and elicits a conditioned response (CR) only after it is paired with an unconditioned stimulus (UCS). (see Pavlov's Discovery)
 - b.* An unconditioned stimulus elicits a reflexive response or an unlearned response that happens automatically. Therefore, a neutral stimulus is not synonymous with an unconditioned stimulus.
 - c.* A neutral stimulus does not elicit any response.

- d.* A neutral stimulus does not elicit any response. A neutral stimulus becomes a conditioned stimulus and elicits a conditioned response only when it is paired with an unconditioned stimulus.
2. *a* is the answer. The conditioned stimulus is the sound of the drill. The unconditioned stimulus is the use of the drill on the teeth. The unconditioned response is the pain that the drill causes. The conditioned response is nausea, which is elicited by the CS, the sound of the drill. (see Pavlov's Discovery)
- b, d.* Reinforcement, both positive and negative, is used in operant conditioning.
- c.* Operant conditioning involves learning an association between a behavior and its consequences. Letitia is learning an association between two stimuli: the sound of the drill and the feeling of the drill on her teeth.
3. *a* is the answer (see below).
4. *d* is the answer (see below).
5. *c* is the answer. Antonio's nausea in response to Ferris wheels is an example of classical conditioning. The conditioned stimulus is the sight of the amusement park. The unconditioned stimulus is the ride on the Ferris wheel. The unconditioned response is feeling dizzy. The conditioned response is feeling nauseated. (see Pavlov's Discovery)
6. *c* is the answer. An organism will generalize by responding to stimuli that are similar to the conditioned stimulus. (see Stimulus Generalization and Discrimination)
- a.* Stimulus generalization is not dependent on whether the CS has occurred in the presence of the UCS. The generalized stimulus just has to be similar to the conditioned stimulus.
- b.* In stimulus generalization, stimuli that are similar to the CS elicit a CR. This response is *always learned*; it is never reflexive.
- d.* Generalization refers to responses made to stimuli that are similar to the CS, not to the UCS.
7. *b* is the answer. Spontaneous recovery is the recurrence of a conditioned response following extinction in the absence of reconditioning. (see Conditioned Responses Over Time: Extinction and Spontaneous Recovery)
- a.* Reconditioning is the re-pairing of the CS and the UCS after extinction. The fire alarm (CS) would have to be paired repeatedly with fire (UCS) again for reconditioning to occur.
- c.* Operant conditioned responses are under stimulus control. This is an example of classical conditioning. The CS is the fire alarm, and the UCS is the fire.
- d.* If stimulus generalization had occurred, the students would have run out of the building in response to an alarm (CS) that was similar but not identical to the original fire alarm. The students heard the same fire alarm in December and September.
8. *a* is the answer. The rat has been classically conditioned to a dark blue light. When he reacts to a turquoise light, he is generalizing his response to a different but similar stimulus. (see Stimulus Generalization and Discrimination)
- b.* If the rat had learned to discriminate between stimuli, then he would not react to any stimulus other than the one that originally predicted the electric shock.
- c.* There is no stimulus degradation in this example.
- d.* Stimulus control occurs with the use of operant conditioning.
9. *b* is the answer. Forward conditioning produces the strongest conditioned responses. The CS is presented prior to the UCS, so it becomes a good predictor of the UCS. (see The Signaling of Significant Events)
- a.* There is no such thing as spontaneous conditioning per se. (You may be thinking of spontaneous recovery, where the conditioned response is elicited after extinction.) But remember, even the spontaneous conditioned response isn't very strong.
- c.* In simultaneous conditioning, the CS and the UCS are presented simultaneously. This is not the strongest conditioning scenario because the CS doesn't predict the UCS and the organism is probably paying more attention to the reflex-producing UCS.

- d.* In backward conditioning, the CS is presented after the UCS. Again, this order of events doesn't allow the CS to become a good predictor of the UCS.
10. *a* is the answer. Biopreparedness is a natural tendency to make certain associations, such as between food and nausea rather than between a sound and nausea. (see The Signaling of Significant Events)
- b.* Tanya did not generalize from one food to another; she associated the food with the nausea.
- c.* In simultaneous conditioning, the CS and UCS arrive at the same time. Tanya didn't experience chemotherapy and food at the same time.
- d.* High signal strength causes more rapid learning but doesn't explain why she had a conditioned response to the food rather than the song.
11. *b* is the answer. Discriminative stimuli allow the organism to discriminate between situations that will produce a consequence—a reinforcer or punishment—and those that will not. (see Basic Components of Operant Conditioning)
- a.* Discriminative stimuli let an organism know when to make a response; they do not cause a response. Conditioned stimuli elicit or cause a conditioned response. There are no conditioned stimuli in operant conditioning.
- c.* Shaping involves rewarding successive approximations of a behavior (behaviors that come closer and closer to the desired response).
- d.* Stimulus generalization in classical conditioning is when a conditioned response is made to a stimulus similar to the conditioned stimulus.
12. *d* is the answer. (see Punishment)
- a, b, c.* These are all true. Punishment is not pleasant for the organism. It is accomplished by presenting an aversive stimulus (getting fired) or taking away a positive stimulus (the privilege of going out on the weekend). Punishment is used to decrease the occurrence of the behavior that precedes it.
13. *b* is the answer. The negative reinforcer is the removal of drilling pain by the anesthetic. The behavior (asking for a drug to deaden the pain) will increase because the negative reinforcer has removed a potentially aversive stimulus (drilling pain). (see Basic Components of Operant Conditioning)
- a.* A positive reinforcer is a pleasant stimulus that is added to the environment following a desired response. In this example, an unpleasant stimulus, pain, is being removed; a pleasant one is not being added.
- c.* If Kent was being punished, his behavior would be followed by an aversive stimulus or the removal of a pleasant one. Being relieved of pain is the removal of an unpleasant stimulus.
- d.* Learned helplessness, the idea that behaviors are not related to consequences, would be applicable here if Kent believed there was nothing he could do to get relief from the pain.
14. *c* is the answer. Anne is not going to tell her boss how she feels about him because she wants to avoid being fired. (see Basic Components of Operant Conditioning)
- a.* Escape conditioning involves learning to respond in order to get away from an already present aversive stimulus. Anne does not refrain from telling her boss what she is feeling in order to escape anything. She is trying to avoid the possibility of an aversive stimulus (getting fired) in the future.
- b.* This is an example of operant, not classical, conditioning. Anne avoids making a behavioral response because she has learned that the consequence of that response is getting fired. She has not learned that one stimulus (CS) predicts the occurrence of another (UCS).
- d.* Discriminative stimuli let an organism know when to respond in order to avoid punishment or receive reinforcement. There are no stimuli in the environment that let Anne know when not to tell her boss that she is angry. She simply knows that she should not yell at her boss. A discriminative stimulus in this question would have been some clue that her boss was in a good mood and therefore more receptive to hearing what she had to say.
15. *c* is the answer. A behavior must occur before it can be reinforced. If an organism has never performed the desired behavior, behaviors that are successive approximations of the desired response are reinforced

until the whole behavior appears. For an example of successive approximation, see the example of teaching your dog to “shake” in your text. (see Forming and Strengthening Operant Behavior)

- a.* Behaviors that are shaped are not always difficult to perform. For example, it is not physically difficult for a dog to roll over, but if the dog has never done so, its behavior must be shaped.
 - b.* Shaping is the creation of a new behavior, not the decreasing of an existing behavior.
 - d.* Shaping allows an organism to learn a new behavior. Reflexive behaviors are not new. Also, conditioned responses are learned, not reflexive.
16. *a* is the answer. When the organism can predict how many responses are necessary for a reward, it will vigorously respond in expectation. (see Forming and Strengthening Operant Behavior)
- b.* On a fixed-interval schedule, an organism will respond in order to receive a reinforcement, then wait until the next interval has passed before responding again.
 - c.* A variable-ratio schedule produces a high response rate but not as high a rate as that produced by a fixed-ratio schedule.
 - d.* A variable-interval schedule produces a slow, steady rate of response.
17. *b* is the answer. Patient B will receive a reinforcer—pain medication—every time he presses a button. The reinforcement will be continuously under his control. (see Forming and Strengthening Operant Behavior)
- a.* Patient A is reinforced after a fixed interval of time, every six hours.
 - c, d.* Patient B’s situation fulfills the criteria for a continuous reinforcement schedule, but Patient A’s does not.
18. *a* is the answer. By watching the commercials, people learn that use of breath mints is rewarded or reinforced by meeting an attractive stranger with whom they will live happily ever after. This is called vicarious conditioning. (see Observational Learning: Learning by Imitation)
- b.* Observation learning does involve learning by watching the behavior of others. But the people being observed do not have to receive a reward or punishment in order for the person watching them to learn. Advertisements, as in this example, usually depict people being rewarded for buying and using the advertised products. Therefore, *a* is the better answer.
 - c.* This is an example of vicarious, not classical, conditioning.
 - d.* There is no stimulus mentioned in the question that lets a person know when to use breath mints. You may have thought that the presence of a stranger of the opposite sex was a discriminative stimulus, but this is not the case. The stranger is the reward or reinforcement in this example.
19. *c* is the answer. Distributed practice has been showed to improve memory because it allows repeated opportunities to use new information. (see Using Research on Learning to Help People Learn)
- a.* Practice does improve memory.
 - b.* Research in cognitive psychology suggests that a single “cram” session will not improve retention of material.
 - d.* Distributed practice is better than massed practice.
20. *d* is the answer. The most effective practice is carried out by learners who make independent choices and actions. And repeated practice is the most critical component of skill learning. (see Using Research on Learning to Help People Learn)
- a.* There is little or no evidence to support “sleep learning” or other effortless learning schemes.
 - b.* Too much coaching during practice may impair later performance.
 - c.* Feedback is necessary. However, if it is provided during the wrestling moves, it may divert John’s attention from understanding his performance. If it is provided on every move, it may have negative effects.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 2 that you answered correctly.

For each question you answered correctly, circle its number. (Quiz 1 numbers are not shaded; Quiz 2 numbers are shaded.) Are there patterns in the types of questions or the topics you got wrong that could direct your further study? Did you improve from Quiz 1 to Quiz 2?

CHAPTER 7

Memory

MULTIPLE-CHOICE QUESTIONS

SAMPLE QUIZ 1

1. Steven heard his instructor say, "Remember to read the short stories by Christie, Cheever, Porter, and Sayers for next week." Because Steven isn't familiar with the names, he remembers them as "Krissy, Cleever, Porter, and Savers." Steven most likely used _____ encoding.
 - a. acoustic
 - b. episodic
 - c. semantic
 - d. visual
2. The memory for how to perform a physical action is called _____ memory.
 - a. episodic
 - b. procedural
 - c. semantic
 - d. short-term
3. A murder investigation is going on at the resort where you are vacationing. The police are asking you for your alibi. What kind of memory do you need to provide an alibi?
 - a. Episodic
 - b. Procedural
 - c. Semantic
 - d. Short-term
4. Nathan doesn't consciously think about an incident from his childhood when a red-haired neighbor gave him candy and comforted him after he skinned his knee. Due to the subconscious influence of that memory, however, Nathan tends to react positively to any red-haired people he meets; therefore, he is being influenced by his _____ memory.
 - a. episodic
 - b. explicit
 - c. implicit

- d. procedural
5. Raquel was still studying ten minutes before her test. As she entered the classroom, she kept repeating the last sentence she had read: "One meter equals approximately 39.37 inches." This is an example of
- elaborative rehearsal.
 - maintenance rehearsal.
 - mnemonics.
 - retrieval.
6. At the same time that Reepal is listening to her father tell about the party the family is planning, Reepal smells popcorn, hears her radio, sees lightning, and feels hot. Reepal is able to transfer the information about the party to her short-term memory primarily because of
- elaborative rehearsal.
 - implicit memory cues.
 - selective attention.
 - transfer-appropriate processing.
7. An immediate memory span is the number of items that
- can be held in the sensory registers.
 - are stored in long-term memory.
 - can be held in semantic codes.
 - can be recalled in perfect order following one presentation of a stimulus.
8. Unrehearsed information stays in short-term memory for no more than
- one second.
 - three seconds.
 - eighteen seconds.
 - forever.
9. Which of the following sentences would require the most chunks in short-term memory if you only knew how to speak English?
- John has many friends.
 - Ich liebe dich.*
 - Je ne sais pas.*
 - .-.-.-.-.-.-. (Morse code)
10. What feature of long-term memory is of the greatest help to money counterfeiters?
- People usually ignore details and encode the general, underlying meaning of information.
 - The dominant type of encoding in long-term memory is visual encoding.
 - The capacity of long-term memory is limited.
 - Long-term memory is dependent on retrieval cues.
11. Vinnie is exasperated. He has gone to the library to look up a book for class. Even though he checked his class notes before he left, he cannot remember the name of the book. What could account for his memory lapse?
- Inefficient storage in sensory memory
 - Information not getting transferred to long-term memory
 - Problems with selective attention
 - Proactive interference
12. Loss of memory for incidents following hippocampal damage is called _____ amnesia.
- retrograde
 - anterograde
 - proactive
 - retroactive
13. Multiple-choice questions are easier to answer than essay questions because multiple-choice questions
- cause more interference.
 - contain more retrieval cues.

- c. use only semantic memory.
 - d. use only procedural memory.
14. Better recall of the first few words of a list from long-term memory is called the _____ effect.
- a. primacy
 - b. recency
 - c. fatigue
 - d. parallel position
15. Alberta is a night owl. She loves to stay up late and study. However, she has so many classes this semester that she is forced to take her calculus class and study calculus in the morning when she is sluggish and a bit sleepy. Alberta's calculus teacher has given the class a take-home test. Alberta should take the test
- a. in the evening.
 - b. in the afternoon.
 - c. in the morning.
 - d. whenever she feels like it.
16. To answer a question such as, "How many legs do spiders have?" a person will most likely use _____ memory.
- a. episodic
 - b. semantic
 - c. sensory
 - d. short-term
17. An officer shows Sarah a box of office supplies believed to have been stolen from her store and then puts them at the back of the room. When Sarah is asked whether the staplers appear to be those stolen from her store, she thinks for a minute about the staplers she recalls seeing in the box and says they are like the ones stolen. To Sarah's surprise, the officer then shows her that there are no staplers in the box! Sarah must have used _____ memories to answer the question.
- a. constructive
 - b. elaborative
 - c. generalized
 - d. implicit
18. Sudden short-term memory overload will most likely cause
- a. decay.
 - b. proactive interference.
 - c. displacement.
 - d. all of the above.
19. Last week Sigrid had to memorize a poem to recite in front of the class. When she rehearsed at home, her mom told her that she had memorized an incorrect word and told her what to say instead. However, Sigrid had memorized the incorrect version so well that she had difficulty learning the correct word. This is an example of
- a. retroactive interference.
 - b. proactive interference.
 - c. anterograde amnesia.
 - d. decay.
20. Akbar has memorized a list of names by imagining each person in a specific spot in his dorm room. One person is in the closet, another is under the bed, one is hanging upside down from the ceiling, and so on. He is using
- a. context dependence.
 - b. distributed practice.
 - c. the encoding specificity principle.
 - d. the method of loci.
- Total Correct (See answer key) _____

SAMPLE QUIZ 2

Use this quiz to reassess your learning after taking Quiz 1 and reviewing the chapter.

1. Al saw a movie called "Fight of the Kodiak" and immediately thought, "Kodiak is a bear, so this is going to have good scenery." Unfortunately, because Al only _____ encoded the name of the movie as "about a bear," he couldn't remember the actual name when someone asked him later what movie he saw.
 - a. acoustically
 - b. procedurally
 - c. semantically
 - d. visually
2. Colleen frequently loses her keys. To find them, she always has to sit and remember where she had them last. This is an example of
 - a. semantic memory.
 - b. procedural memory.
 - c. episodic memory.
 - d. acoustic encoding.
3. As Kaliina completes a personal history questionnaire, she recalls her birthdate, names of schools she's attended, and relatives' names. Suddenly, she feels hot, flushed, and embarrassed, but doesn't know why. Kaliina's mom realizes that Kaliina subconsciously remembers the time she filled out a similar form and then fainted. When Kaliina tries to remember her personal information, she is using _____ memory; when she feels embarrassed, she is using _____ memory.
 - a. episodic; semantic
 - b. semantic; episodic
 - c. implicit; explicit
 - d. explicit; implicit
4. Which of the following would be most effective for encoding information into long-term memory?
 - a. Chunking
 - b. Maintenance rehearsal
 - c. Elaborative rehearsal
 - d. Serial rehearsal
5. As Laura reads her psychology textbook, the image of each word is stored long enough to be processed and understood. Laura's _____ memory holds the images just long enough to allow stimulus identification to begin.
 - a. long-term
 - b. semantic
 - c. sensory
 - d. short-term
6. Ever since her accident, Rita has to constantly remind herself of what she is doing or else she forgets. For instance, when driving she has to post a note on her dashboard with her destination. Without these notes, she forgets where she is going and has to stop until she remembers again. Rita's _____ memory was damaged in the accident?
 - a. sensory
 - b. working
 - c. long-term
 - d. procedural
7. Aaron could not remember the title of his favorite movie, even when he heard its popular theme song. Only when he saw a huge snow drift that reminded him of an iceberg did he recall the title "Titanic." What might account for Aaron's memory lapse, since the theme song would appear to be a better retrieval cue than a snow drift?
 - a. Context dependence
 - b. The recency effect
 - c. The encoding specificity principle

- d. Displacement
- 8. Albert witnessed an accident last summer in which a van sped through a red stoplight and broadsided a van. Shortly after the accident, when asked if the van ran a red stop sign, Albert correctly said, "No, it was a stoplight." However, six months later when he was a witness in court and was asked whether the van ran a red light or a red stop sign, Albert couldn't remember. What could account for this memory problem?
 - a. The encoding specificity principle
 - b. Constructive memory
 - c. Spreading activation
 - d. Problems with selective attention
- 9. Remembering the phone number 217-1967 as your birthday, February 17, 1967, is an example of
 - a. chunking.
 - b. the Brown-Peterson procedure.
 - c. the SQ3R method.
 - d. the method of loci.
- 10. Ted showed his third-graders pictures of famous presidents. To quiz them, he gave them clues about what these people looked like. For example, "He wore a big black hat, enjoyed reading by the fireplace, was very, very tall, and had a black beard." These clues will function as
 - a. retrieval cues.
 - b. primacy cues.
 - c. contextual codes.
 - d. acoustic codes.
- 11. Context dependence means that information is easier to remember when
 - a. it is organized, for example, in an outline.
 - b. people are in the same place as they were when they learned the material.
 - c. people are in the same psychological state of mind as they were when they learned the material.
 - d. a mnemonic is used.
- 12. When Molly tried to remember the name of the actor who portrayed Dr. Eilam on her favorite TV program, she could see the first letters, but could not think of the name. Molly's experience of the tip-of-the-tongue phenomenon is caused by retrieval of incomplete information from her
 - a. constructive memory.
 - b. sensory memory.
 - c. semantic networks.
 - d. schemas.
- 13. If you lost the ability to retrieve any information from long-term memory, you would not be able to
 - a. chunk information.
 - b. recognize information in sensory memory.
 - c. use the method of loci.
 - d. All of the above
- 14. Marcie was in a really bad mood when she recalled the day of her graduation from college. What will she be most likely to remember?
 - a. Mostly negative incidents
 - b. Mostly positive incidents
 - c. Negative and positive incidents equally
 - d. She will have trouble recalling much of anything
- 15. Which of the following statements is *not* supported by recent research in the area of false memories?
 - a. It is fairly easy to create false memories of events.
 - b. False memories can be as vivid as accurate ones.
 - c. People may be more likely to forget unpleasant events than to forget pleasant events.
 - d. People are less confident of false recovered memories than of accurate memories.

16. Retroactive interference occurs when
- new information interferes with the ability to recall old information.
 - old information interferes with the learning of new material.
 - old information decays.
 - new information decays.
17. When Robin moved to a new state, her new teacher told her that the class was learning the names of all the presidents. Robin was horrified. She had painstakingly memorized all those names the year before and could not remember very many of them. To her surprise, however, learning them the second time took much less time than it had the first time. This is an example of
- mnemonics.
 - release from proactive interference.
 - savings.
 - state dependence.
18. Jen has hippocampus damage; therefore, she has memory problems. Which of the following will she most likely be unable to do?
- Learn how to solve a puzzle
 - Remember the names of new people she met ten minutes ago.
 - Remember a childhood birthday party
 - Remember how to ride a bike
19. Mentally placing objects in specific geographic locations in order to remember them more efficiently is called
- the method of loci.
 - procedural memorization.
 - use of retrieval cue.
 - context dependence.
20. Jacques was so involved in his social life his first semester that he almost flunked out. At the beginning of second semester, he asked his friends for their advice. Which friend should he *not* listen to?
- Friend 1: "Read the material a second time."
 - Friend 2: "Create an outline for your lecture notes. You need to mentally organize the material somehow."
 - Friend 3: "Ask yourself questions about the material as you read, and then look for the answers in the text."
 - Friend 4: "Try to relate the material to information you already know."

Total Correct (See answer key) _____

ANSWERS TO MULTIPLE-CHOICE QUESTIONS

Circle the question numbers you answered correctly.

Sample Quiz 1

1. *a* is the answer. When acoustic codes are used the errors likely to be made are errors in remembering the sound of the words. (see Basic Memory Processes)
 - b*. Episodic memories are those of events you witnessed, but episodic is not a type of encoding.
 - c*. Semantic encoding represents the meaning of the information. If Steven had used semantic encoding, he might have remembered something about the meaning of the names (assuming he was familiar with them, which he wasn't) such as the titles of the stories or the homelands of the authors.
 - d*. Visual encoding would require a visual stimulus, but the instructor just said the names.
2. *b* is the answer. Remembering how to do something is procedural memory. (see Types of Memory)
 - a*. Episodic memories are memories of events that occurred while you were present, such as the memory of your first day at school.
 - c*. Semantic memories are memories of generalized knowledge, such as remembering the tribal names of the Plains Indians.
 - d*. Remembering how to do something isn't necessarily a short-term memory. It could be in long-term memory.
3. *a* is the answer. Where you were at the time of the murder would be a memory of an episode at which you were present. This is episodic memory. (see Types of Memory)
 - b*. Procedural memories involve how to do something or how to carry out a procedure.
 - c*. Semantic memories involve general knowledge.
 - d*. Short-term memory is where episodic, procedural, and semantic memories can be stored for about 18 seconds, but this wouldn't be long enough to use in answering questions about your whereabouts.
4. *c* is the answer. Implicit memories are not purposefully recalled but do influence behavior. (see Explicit and Implicit Memory)
 - a*. Episodic memories are memories of events, but Nathan has not recalled the childhood event; therefore, it is not what is influencing him.
 - b*. Explicit memories are those we purposely try to remember. Nathan has not tried to remember the childhood incident, nor has he remembered it.
 - d*. Procedural memories are skill memories. Nathan is not recalling a skill like bike riding, he is being influenced by a subconscious childhood memory.
5. *b* is the answer. Maintenance rehearsal is a method of keeping information in short-term memory. Raquel is trying to keep in short-term memory the most recently read information. (see Models of Memory)
 - a*. Elaborative rehearsal occurs when new information is related to old information in long-term memory. If Raquel tried to integrate the number of inches in a meter with other information about the metric system, she would have been using elaborative rehearsal.
 - c*. Mnemonics are strategies for creating a new context for material in order to recall it later. Raquel was not doing anything other than repeating the information. She did not use mental imagery or the method of loci.
 - d*. Raquel was trying to keep the information in storage, not trying to retrieve it.
6. *c* is the answer. Selective attention allows the most important information processed by the sensory registers to be retained in short-term memory. (see Sensory Memory)
 - a*. Rehearsal is not described as having used elaborative rehearsal. Elaborative rehearsal would be relating new information to old information.

- b.* Implicit memory is the unintentional recall and influence of prior experiences, but there is no such thing as an implicit memory cue.
- d.* Transfer-appropriate processing is when encoding method matches retrieval method.
7. *d* is the answer. An immediate memory span or the capacity of short-term memory is that amount of information a person can remember after one presentation of a stimulus. (see Short-Term Memory and Working Memory)
- a.* An unlimited amount of information can be stored in sensory memory, but only for a short time.
- b.* There is no span or limit on the amount of information that can be stored in long-term memory.
- c.* Items in memory can take the form of a semantic code, but items are not stored *in* semantic code.
8. *c* is the answer. Unrehearsed information stays in short-term memory for about eighteen seconds. (see Short-Term Memory and Working Memory)
- a, b.* Information in the sensory registers is maintained for no more than a few seconds.
- d.* Information may stay in long-term memory until death, unless it decays.
9. *d* is the answer. Morse code uses a different "alphabet" than English does. A person who does not know Morse code would not have any information in long-term memory that would help put more than one symbol into one chunk. Therefore, the Morse code statement (which translates as the one-word sentence "No") would require the greatest number of chunks in short-term memory. (see Short-Term Memory and Working Memory)
- a.* The entire sentence could be one chunk for a native English speaker.
- b, c.* Both French and German use the same alphabet as English. Therefore, each word would be a chunk because information stored in long-term memory would help recognize the letters as words. However, each dot or dash of a Morse code letter would be one unit of new information, causing that statement to require a greater number of chunks.
10. *a* is the answer. Because semantic encoding is the dominant form of encoding in long-term memory, people often encode the general meaning of visual stimuli rather than specific details. Therefore, people will tend to recognize the monetary significance of a twenty-dollar bill but may miss the fine visual differences between fake twenty-dollar bills and authentic bills. (see Long-Term Memory)
- b.* Semantic encoding is dominant in long-term memory. If visual encoding were dominant, counterfeiters would have a more difficult time passing off fake bills.
- c.* The capacity of long-term memory is unlimited. This feature would be a hindrance to counterfeiters because people can recall previous information they received on distinguishing real bills from fake bills.
- d.* Retrieval cues can aid recall, but long-term memory is not totally dependent on such cues. Even if it were, this could still be a hindrance to a counterfeiter. A slightly different feel or look to a bill could be a cue that might help people recognize that a bill is different and suspicious.
11. *b* is the answer. When Vinnie remembered what it was he needed, he put that information into short-term memory. He then probably became distracted before the memory was transferred into long-term memory. (see Long-Term Memory)
- a, c.* If Vinnie checked his class notes before he left for the library, information had probably already been processed and transferred from sensory to short-term memory. Selective attention determines what is held in the sensory registers for further processing.
- d.* Proactive interference occurs when old information in long-term memory interferes with remembering new information. In Vinnie's case there is no suggestion of interference: he just can't remember.
12. *b* is the answer. As described in the famous case of HM in your text, damage to the hippocampus results in anterograde amnesia—the inability to form new long-term memories. (see Brain Structures and Memory)
- a.* Retrograde amnesia is the inability to remember what happened before damage or injury.
- c, d.* There is no such thing as proactive or retroactive amnesia. (You are probably thinking of proactive and retroactive interference.)

13. *b* is the answer. The answer to a multiple-choice question is listed on the page. It will act as a retrieval cue by helping you recognize information stored in long-term memory. (see Retrieval Cues and Encoding Specificity)
- a.* Answering multiple-choice questions actually creates less interference. Retrieval cues decrease the effect of interference.
 - c.* A good answer to an essay question would require more extensive semantic memory than would a multiple-choice answer.
 - d.* Neither multiple-choice questions nor essay questions use only procedural memories.
14. *a* is the answer. Better recall of the first few words of a list from long-term memory is called the primacy effect. (see Distinguishing Between Short-Term and Long-Term Memory)
- b.* Better recall of the last few words of a list from short-term memory is called the recency effect.
 - c.* There is no such thing as the fatigue effect.
 - d.* There is no such thing as the parallel position effect.
15. *c* is the answer. Taking the test in the morning lets Alberta's state of mind act as a retrieval cue (utilizes state-dependent memory). (see Context and State Dependence)
- a, b, d.* At any other time of the day, Alberta would not be in the same psychological state as she was when she learned the material.
16. *b* is the answer. Semantic memory contains general knowledge that isn't linked to a particular event. (see Types of Memory)
- a.* Episodic memory would not answer a question about facts that are not related to a personally experienced event.
 - c.* A person uses sensory memory to hear or read a question, but in order to answer the question the person must draw upon information in the semantic memory.
 - d.* Short-term memory lasts only 18 seconds; therefore, it would be unlikely to contain the answer to a question of general knowledge.
17. *a* is the answer. Constructive memories can be very vivid. Sarah probably thought that staplers would be likely to be in the box of office supplies and accidentally created a memory of their image. (see Constructing Memories)
- b.* There is no such thing as elaborative memories. Elaborative rehearsal is the term for linking new information to old information. Sarah was probably not rehearsing the information about what was in the box.
 - c.* Generalized memories is not a term. You may have been thinking of semantic memories, but Sarah was not using her semantic memory to create the memory of a stapler.
 - d.* Implicit memories are actual memories that we have not tried to retrieve but that affect us anyway. Since there were no staplers in the box, Sarah couldn't have an implicit memory of them.
18. *c* is the answer. Overloading short-term memory causes interference with old information through displacement. Short-term memory can hold only a limited amount of information; new information literally squeezes out old information because of inadequate space. (see Why Do We Forget?: The Roles of Decay and Interference)
- a.* Memories that decay disappear gradually. When short-term memory is suddenly overloaded, old information doesn't slowly decay; rather, it is quickly displaced.
 - b.* Proactive interference occurs when old information prevents the learning of new information. When short-term memory is overloaded, the old information is lost, and the new information is stored.
 - d.* Only *c* is the answer.
19. *b* is the answer. Proactive interference occurs when the process of remembering new information is disrupted by the presence of old information. The old, incorrect version of the poem that Sigrid had memorized kept getting in the way of her learning the correct word. (see Why Do We Forget?: The Roles of Decay and Interference)

- a.* For retroactive interference to be the correct answer, learning the new word in the poem should have interfered with Sigrid's ability to remember the old, incorrect version of the poem. Retroactive interference refers to new information disrupting the recall of old information.
 - c.* Anterograde amnesia is the inability to form new memories after hippocampal damage. Sigrid's hippocampus was intact.
 - d.* Decay is the gradual disappearance of a memory. Sigrid would have had to learn the new word and then forget it for this to be the right answer.
20. *d* is the answer. Akbar is using the method of loci to mentally place people in various spots in his dorm room. When he needs to remember these people, he will mentally look for them in his dorm room. (see Improving Your Memory)
- a.* Akbar is using imagery, not his current environment (context), to recall information.
 - b.* Distributed practice is taking a break between study sessions instead of "cramming." Akbar is not described as taking study breaks.
 - c.* The encoding specificity principle refers to the similarity between information when it is learned and when it is retrieved. This is not a mnemonic.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 1 that you answered correctly.

ANSWERS TO MULTIPLE-CHOICE QUESTIONS

Circle the question numbers you answered correctly.

Sample Quiz 2

- 1. *c* is the answer. Semantic encoding is a meaning code, which makes it less likely that exact words (such as in a title) will be recalled, although the topic may be recalled. (see Basic Memory Processes)
 - a.* Acoustic encoding represents what something sounds like. If Al had acoustically encoded the movie title, he might have remembered the exact words, or words that sounded similar.
 - b.* Procedural memory is the knowledge of how to do something; it is not a type of encoding.
 - d.* Visual encoding stores images. Al encoded the meaning of the title, not an image of it.
- 2. *c* is the answer. Colleen has to remember where she was when she last had her keys. This is episodic memory; she will be present in the remembered event. (see Types of Memory)
 - a.* Semantic memories are of general knowledge. Since Colleen is trying to remember an incident or episode that involves her presence, this cannot be the answer.
 - b.* Procedural memories are of how to do something. Colleen is trying to remember an episode, not a procedure.
 - d.* Acoustic memory is for sounds. Colleen is trying to remember where she left her keys, not what sound they made.
- 3. *d* is the answer. Trying to recall personal information is using explicit memory; accidentally being influenced by a subconscious memory is an effect of implicit memory. (see Explicit and Implicit Memory)
 - a, b.* Kaliina is not remembering an episode from her life nor general knowledge.
 - c.* Implicit memories unintentionally influence us; they are not the intentional recall of personal information. (See *d.*)
- 4. *c* is the answer. Elaborative rehearsal, which is relating the new information to be remembered to information in long-term memory, is an effective way of encoding information into long-term memory. (see Models of Memory)
 - a.* Chunking is an effective method for storing information in short-term memory.
 - b.* Maintenance rehearsal is an effective method for retaining information in short-term memory.
 - d.* There is no such thing as serial rehearsal.

5. *c* is the answer. Sensory memory lasts about a second, then the information is transferred to short-term memory or lost. (see Sensory Memory)
- a.* Long-term memory can last for years; it is not a sensory register.
 - b.* Semantic memory is part of long-term memory. A network links information.
 - d.* Short-term memory is involved in reading, but it is not a sensory register.
6. *b* is the answer. Short-term or working memory uses information in the immediate present (18 seconds). Rita cannot keep information in her working memory long enough to accomplish a task, such as making correct judgments in order to reach her destination. (see Short-Term Memory and Working Memory)
- a.* Sensory memory holds information only long enough for it to be processed further and recognized. Laura recognizes her surroundings; she just forgets why she is there.
 - c.* Laura's long-term memory is fine. When she stops and thinks about it, she is able to recall her destination and how to get there.
 - d.* Laura's procedural memory, her skill memory, appears to be fine—she is driving.
7. *c* is the answer. The encoding specificity principle suggests that the effectiveness of cues aiding memory retrieval depends on the degree to which they tap into information that was first encoded. Aaron probably semantically encoded "Titanic" into long-term memory. The semantic cue of a drift that resembled an iceberg overrode the acoustic cue of the theme song. (see Retrieval Cues and Encoding Specificity)
- a.* Context dependence suggests that memories can be helped or hindered by similarities in the environment. This question says nothing about Aaron's environment at the time of viewing the movie or at the time of recall.
 - b.* The recency effect refers to recalling words easily from the end of a list. It does not apply here.
 - d.* Displacement is a result of interference, when retrieval of information is impaired by the presence of other information. Aaron's problems were with retrieval cues. The information was still intact; the problem was how to get to it.
8. *c* is the answer. Memories are stored in networks. When one part of the network is activated, related areas will also be activated. Albert already had memories of the two stop signals in connection with the accident. So when he was asked to recall what happened, the activation spread to all related memories. (see Retrieval from Semantic Memory)
- a.* Encoding specificity suggests that corresponding encoding strategies and retrieval cues will aid recall. There is nothing in this question about different types of encoding.
 - b.* The spreading activation could lead to constructive memory. But in this case, Albert has not constructed a memory—he just can't remember.
 - d.* In sensory memory, selective attention controls what information will be processed further. Selective attention has no application here.
9. *a* is the answer. Chunking is the ability to group information into a meaningful unit that can be stored in short-term memory. (see Short-Term Memory and Working Memory)
- b.* The Brown-Peterson procedure is used to determine how long unrehearsed information remains in short-term memory.
 - c.* The SQ3R method is a way to read a textbook by surveying, questioning, reading, reciting, and reviewing.
 - d.* The method of loci is a mnemonic.
10. *a* is the answer. Ted has listed features that should help his students recognize the correct information stored in long-term memory: the name *Abraham Lincoln*. (see Retrieval Cues and Encoding Specificity)
- b.* Primacy cue is not a term. You may have been thinking of primacy effect.
 - c, d.* When Ted's students hear his question, the clues will enter sensory memory as acoustic codes and then, after further processing, will enter short-term memory. However, the students will use the clues in short-term memory, not the acoustic codes, as retrieval cues to help them pull information out of long-

term memory. There is no such thing as contextual coding. You may have been thinking of context dependence.

11. *b* is the answer. It is easier to remember material when you are in the place where you originally learned it. The surrounding environment acts as a retrieval cue. (see Context and State Dependence)
 - a.* Organizing material in an outline is one way to remember it more easily later on, but context dependence doesn't refer to this.
 - c.* State dependence occurs when people find it easier to recall material when they are in the same psychological state of mind as they were when they learned the information. A psychological state acts as a retrieval cue.
 - d.* Using mnemonics can improve your memory, but this is not the same thing as context dependence.
12. *c* is the answer. Semantic networks are links of related information. When a person recalls information from one node of the network, it can feel as if the person is very close to accessing the information needed in the next node. (see Retrieval from Semantic Memory)
 - a.* Constructive memory is a fabricated, but seemingly real, recollection.
 - b.* Sensory memory lasts only a second or so; Molly is using her long-term memory.
 - d.* Schemas are mental representations of categories and do not explain the tip-of-the-tongue phenomenon.
13. *d* is the answer. In order to chunk, you must use the information in long-term memory to help you group items into one chunk in short-term memory. The ability to recognize something in sensory memory involves retrieving a similar pattern of information or material from long-term memory. In order to use the method of loci, you must retrieve knowledge about a specific location or loci stored in long-term memory. (see Long-Term Memory)
14. *a* is the answer. We tend to remember incidents congruent with our moods. (see Context and State Dependence)
 - b.* Marcie would be more likely to recall positive events if she were in a positive mood, not a negative mood.
 - c.* Our memories tend to correspond to our moods.
 - d.* Our moods tend to elicit memories similar to them. Our moods do not impair memories.
15. *d* is the answer. Part of the controversy surrounding recovered memories is that people are extremely confident of their memories because they are so vivid, even though these memories may be inaccurate. To date there is no incontrovertible way to distinguish the experience of a true memory from the experience of a false memory. (see Thinking Critically: Can Traumatic Memories Be Repressed, then Recovered?)
 - a, b, c.* All of these statements are supported by research on false memories.
16. *a* is the answer. The presence of new information displaces old information in short-term memory. (see Why Do We Forget?: The Roles of Decay and Interference)
 - b.* Proactive interference occurs when old information disrupts the learning of new information.
 - c, d.* Decay is the gradual disappearance of memories.
17. *c* is the answer. Ebbinghaus discovered that relearning took much less time than learning. Savings is the difference between learning and relearning time. (see How Do We Forget?)
 - a.* A mnemonic is a memory strategy that involves placing information in an organized context. In this question, Robin did not use any strategies or methods to relearn the names of the presidents.
 - b.* Release from proactive interference occurs when new information differs so greatly from old information that the old information interferes less with the learning of the new information. Robin is trying to relearn exactly the same information. There is no new information with which the old information can interfere.
 - d.* Because state dependence means that cues from your physical state help you to remember, Robin would have to be in the same state (mood, arousal level, etc.) she was when she first learned the names

of the presidents. Not only is this not mentioned specifically in the description of her situation, but it also is unlikely that a person would be in *one* state when learning such a large amount of information.

18. *b* is the answer. Hippocampal damage usually results in anterograde amnesia, which is the inability to form new memories. Procedural memory formation and recall appear to be unaffected, however. (see Brain Structures and Memory)
- a, d.* Both of these are procedural memories. She could learn to solve a puzzle or could remember how to ride her bike.
- c.* Recall of a childhood event would be unaffected by anterograde amnesia.
19. *a* is the answer. The method of loci involves mentally placing objects in various spots in a familiar location (loci). (see Improving Your Memory)
- b.* Procedural memorization is not a term. You may have been thinking of procedural memory, which is skill learning, but this is not the same as imagining items in locations.
- c.* Using a retrieval cue helps you recognize or retrieve material from long-term memory. Using mnemonics is a method of encoding by organizing information in a certain way.
- d.* Context dependence occurs when the environment (context) acts as a retrieval cue.
20. *a* is the answer. Just rereading the material is not an effective way to learn information from a text. (see Improving Your Memory)
- b, c, d.* These are all good study habits to adopt.

For each question you answered correctly, circle its number. (Quiz 1 numbers are not shaded; Quiz 2 numbers are shaded.) Are there patterns in the types of questions or the topics you got wrong that could direct your further study? Did you improve from Quiz 1 to Quiz 2?

CHAPTER 8

Cognition and Language

MULTIPLE-CHOICE QUESTIONS

SAMPLE QUIZ 1

1. James is taking a keyboarding test of speed and accuracy. He wants to do well enough to be hired for temporary work during the summer break. His normal speed is 65 words per minute (wpm), but he is tempted to try to make 85 wpm to ensure summer employment. What reaction time problem will James probably encounter?
 - a. Stimulus-response compatibility
 - b. Expectancy
 - c. Speed-accuracy tradeoff
 - d. Decision complexity
2. Halle watches mayonnaise jars going by on an assembly line and is supposed to grab any jars with crooked lids or two labels. Halle's reaction time will most likely decrease if she
 - a. also has to look for underfilled jars or crooked labels.
 - b. doesn't know when the defective jars come by.
 - c. tries to be extremely careful not to grab a good jar.

- d. only has to watch for crooked lids.
3. A _____ is a mental representation of familiar parts of your world
- cognitive map
 - reconstructive memory
 - directional bias.
 - None of the above
4. Propositions
- are the basic components of words.
 - show the relationships among concepts.
 - are always true.
 - show the relationship among mental models.
5. Try to figure out the name of the natural concept to which the following four items belong, and then choose the prototypical example of that concept.
- A fist
 - A brick
 - A gun
 - Sharp fingernails
6. An algorithm
- is a shortcut to the solution of a problem.
 - will sometimes yield a correct answer to a problem.
 - will always yield a correct answer to a problem.
 - is subject to bias from the availability heuristic.
7. If the temperature falls below 32 degrees Fahrenheit, any precipitation that falls will be in the form of snow. Then if it is now 37 degrees Fahrenheit outside and about to storm, we should expect rain. These statements are an example of
- rules of logic.
 - a counterfactual argument.
 - the confirmation bias.
 - informal reasoning.
8. In the classic fairy tale, when the prince wants to find Cinderella after she runs from the ball at midnight, he first uses a(n) _____ strategy and checks only estates in the kingdom where women of her beauty and refinement would most likely live. When that doesn't work, he uses a(n) _____ strategy and conducts a house-to-house search.
- schematic; heuristic
 - algorithmic; heuristic
 - heuristic; algorithmic
 - schematic; algorithmic
9. Many senior citizens lose thousands of dollars each spring because they place unwarranted trust in neatly dressed, clean-cut, polite young men who come to their houses and advise them that they need roof repairs. The seniors put down a substantial deposit for work to be done, only to realize later that the men are not going to return and no work was actually needed. They fall prey to this scam because of the
- confirmation bias.
 - anchoring heuristic.
 - availability heuristic.
 - representativeness heuristic.
10. "An action potential fires 'all or none' like a gun," says Jamila. Jamila is using _____ to help her understand the concept of threshold.
- an analogy
 - decomposition
 - negative evidence
 - a script

11. Functional fixedness occurs when a person
 - a. uses old solutions to solve new problems.
 - b. looks only for information that will confirm a hypothesis.
 - c. ignores negative evidence.
 - d. cannot think of novel uses for familiar objects in order to solve a problem.
12. While trying to balance equations in a chemistry assignment, Luna uses the same method of working through the first ten problems. On the eleventh problem, however, a completely different approach is necessary and Luna can't figure out what it is. Luna most likely developed
 - a. an algorithm.
 - b. functional fixedness.
 - c. a mental model.
 - d. a mental set.
13. Luna (see question 12 above) decides to forget about the problem for a while at dinner. When she returns to her room, she realizes how to solve the problem. Luna used _____ to solve the problem.
 - a. deep structures
 - b. expert systems
 - c. incubation
 - d. prototypes
14. Raymond recently won \$500 in a lottery drawing. He won't buy any more tickets at the store that sold him his winning ticket because he thinks he's used up his luck at that store. This is an example of
 - a. the gambler's fallacy.
 - b. loss aversion.
 - c. ignoring negative evidence.
 - d. the confirmation bias.
15. The utility of a choice in decision making refers to which of the following?
 - a. The likelihood of that choice being the actual outcome
 - b. One's personal perception of its value
 - c. The perception of its risk
 - d. All of the above
16. The deep structure of a sentence is
 - a. the sequence of words in the sentence.
 - b. the meaning of the sentence.
 - c. the syntax of the sentence.
 - d. a reflection of the complexity of the sentence.
17. Every Sunday morning Juan and his roommate jogged to the Hotcake House, where they ate a leisurely breakfast while reading the Sunday *New York Times*. When Juan's roommate was called out of town for two weeks, disrupting their normal routine, Juan lost track of what day of the week it was. What aspect of Juan's Sundays was affected?
 - a. His schema
 - b. His script
 - c. His mental model
 - d. His image
18. Many advertising campaigns designed for foreign countries have failed because the words in the ads had the wrong meanings in other languages. For example, Nova, the name of a car, means "does not go" in Spanish. The advertisers did not consider the _____ of the Spanish language when creating the ad.
 - a. syntax
 - b. language acquisition device
 - c. semantics
 - d. surface structure

19. Context can alter the interpretation of a sentence. Which of the following would not be considered a part of context?
- A person's knowledge of the world based on experience
 - The situation in which the communication is taking place
 - The inflection of a person's voice when communicating
 - All of the above contribute to the context of a situation.
20. Which statement is *true* regarding bilingualism?
- Children who are bilingual tend to have less cognitive flexibility.
 - Trying to learn two languages at once before the critical period can impair learning of one of the languages.
 - Trying to learn two languages at once before the critical period can impair learning of both languages.
 - Children with equal mastery of two languages seem to show more creativity.

Total Correct (See answer key) _____

SAMPLE QUIZ 2

Use this quiz to reassess your learning after taking Quiz 1 and reviewing the chapter.

- Reaction time is the
 - time it takes to perceive a stimulus.
 - time it takes to react to a stimulus after it has been perceived.
 - time it takes to react to a stimulus after it has been presented.
 - timing of mental events.
- Lianne is staying overnight at a friend's home. She gets up in the middle of the night to go to the bathroom, and runs smack into a wall. Lianne is using an incorrect
 - proposition.
 - schema.
 - cognitive map.
 - script.
- Cliff has just stopped his car at a red light when the light changes to green. Which of the following will affect his reaction time?
 - Cliff is driving a stick shift for the first time.
 - Cliff did not expect the light to change to green so quickly.
 - Five roads intersect at this light. Cliff can turn onto one of these roads or go straight ahead.
 - All of the above.
- The smallest segments of knowledge that can stand as individual assertions are called
 - schemas.
 - propositions.
 - sylogisms.
 - scripts.
- Natural and formal concepts differ in that
 - formal concepts provide a way to classify objects, whereas natural concepts do not.
 - natural concepts provide a way to classify objects, whereas formal concepts do not.
 - formal concepts are fuzzy and sometimes difficult to define, whereas natural concepts are rigidly defined.
 - natural concepts are fuzzy and sometimes difficult to define, whereas formal concepts are rigidly defined.
- Lance found a dollar in the stairway of the apartment building. Nevertheless, he was still upset because the soda machine in the lobby had taken his four quarters but had not released any beverage. Lance's preoccupation with the soda machine is an example of
 - loss aversion.
 - gambler's fallacy.
 - negative expected value.

- d. decomposition.
7. You would use a _____ when thinking about how to record on a VCR.
- schema
 - script
 - mental model
 - proposition
8. Clinton is really frustrated. His uncle has been beating him at checkers all night. He is going to play another game, but this time he is going to base his strategy on an algorithm, not a heuristic. What problem will this cause?
- Clinton still may not win the game.
 - Clinton and his uncle may be playing the same game of checkers for a very long time.
 - Clinton is ignoring overall probabilities.
 - The representativeness heuristic will bias Clinton's choice of strategy.
9. Cindy is 100 percent positive of her ability to find an advertising job in New York City. When she gets to New York, she reads in the paper that jobs are extremely scarce because of the large number of recent corporate mergers. Despite this, she is still 90 percent sure that, with her qualifications, she will land a job. Which heuristic is responsible for her reasoning?
- The anchoring heuristic
 - The availability heuristic
 - The representativeness heuristic
 - The base-rate information heuristic
10. Many companies are reporting an inability to staff their foreign offices in Europe. Employees previously interested in overseas work are frightened of the terrorist activity they keep hearing about in the news. They are sure that something disastrous will happen to their families if they move to Europe. Which heuristic are the employees using to assess the incidence of terrorist activities?
- The availability heuristic
 - The representativeness heuristic
 - The anchoring heuristic
 - None of the above
11. What is the main problem with expert systems?
- They are overly difficult to set up.
 - They are successful only in very narrowly defined fields.
 - A group of experts can develop mental sets.
 - Computer-made analogies often do not reflect the real world.
12. The representativeness heuristic causes us to
- ignore overall probabilities.
 - give improper weight to contradictory evidence when making a decision.
 - focus on solutions that are easily brought to mind.
 - consider only those hypotheses with which we are the most familiar.
13. Mike and Cal are marketing executives working as a team for a Fortune 500 company. They have been given an extremely difficult project: They are to design a new consumer product. Mike wants to review all the market research on consumer needs, identify what the product must do to solve those needs, and then see if his company can build it. Cal wants go to the library and look up case histories of other companies in similar situations noted for developing brilliant new products. Mike wants to use a(n) _____ process to solve the problem, and Cal is trying to use a(n) _____ to solve the problem.
- analogy; decomposition
 - working backward; analogy
 - analogy; visual representation
 - incubation; visual representation
14. Winnie, a teacher, has been told that the test scores of one of her new students, Nelson, suggest that he is very bright. The principal has asked her to keep an eye on Nelson and let him know what she thinks

of Nelson's intelligence. All through the first six weeks of the semester, she finds many examples that seem to show that Nelson is indeed very bright. However, during the seventh week, she finds out that the records have been mixed up. Nelson's actual test scores show him as being strictly average. What explains Winnie's observations during the first six weeks?

- a. Confirmation bias
 - b. Functional fixedness
 - c. Mental set
 - d. Decomposition
15. Emmeline works as a lab technician in a neurobiological laboratory. She has just received an announcement that must be posted in the lab immediately. Because she cannot find any thumbtacks, she uses the ends of hypodermic needles to attach the announcement to the bulletin board. What pitfall in problem solving has Emmeline just avoided?
- a. Functional fixedness
 - b. Confirmation bias
 - c. Ignoring of negative evidence
 - d. Faulty hypothesis testing
16. Gambler's fallacy occurs when people
- a. overestimate the probability of very rare events.
 - b. overestimate the probability of very common events.
 - c. are overconfident about their predictions.
 - d. believe that if they fail several times to get "heads" on a coin flip, their next attempt will probably be a success.
17. The newspaper headline reads, "Campus police start operation to run down jaywalkers." This statement has two
- a. deep structures.
 - b. surface structures.
 - c. morphemes.
 - d. phonemes.
18. Which of the following is correct?
- a. Phonemes make up morphemes, which make up words.
 - b. Morphemes make up phonemes, which make up words.
 - c. Words make up morphemes, which make up sentences.
 - d. Words make up phonemes, which make up morphemes.
19. Which of the following sentences would be the easiest to memorize? (1) A grickly aftla hicktored the bubla. (2) Oftla grick hickt bubla.
- a. The first sentence
 - b. The second sentence
 - c. Both will be equally easy to memorize.
 - d. The answer cannot be determined.
20. In Tarzan movies, a husband, his wife, and their baby are shipwrecked. The baby survives and is raised by apes until a doctor finds him twenty years later. The doctor takes the wild man out of the jungle, teaches him to speak French and English, and introduces him to society. Although the wild man's accents are not perfect, he manages to live in England for some time before choosing to go back to the jungle. Why are these movies unrealistic?
- a. A language acquisition device needs to be learned.
 - b. A critical period may exist for language acquisition.
 - c. The wild man should have been able to learn proper French and English accents.
 - d. All of the above.

Total Correct (See answer key) _____

ANSWERS TO MULTIPLE-CHOICE QUESTIONS

Circle the question numbers you answered correctly.

Sample Quiz 1

1. *c* is the answer. The faster James types above his normal speed, the more liable he is to make errors. (see Measuring Information Processing)
 - a.* Stimulus-response compatibility doesn't apply here. The scenario says nothing about a problem with a different keyboard; therefore, it may be assumed that James will be comfortable enough to produce his normal 65 wpm accurately.
 - b.* Expectancy doesn't fit. The scenario says nothing about James's expectations of the material to be typed.
 - d.* The number of actions carried out in keyboarding is limited, and James is familiar with them.
2. *d* is the answer. If the task were less complex, Halle's reaction time would decrease. (see Measuring Information-Processing)
 - a.* If she needed to look for two additional problems, Halle's reaction time would increase, or lengthen.
 - b.* If Halle didn't know when to expect the jars, her reaction time would increase. People who anticipate stimuli can respond more quickly.
 - c.* Halle would be making the speed-accuracy tradeoff if she tried to be very careful not to grab a good jar.
3. *a* is the answer. A cognitive map is a mental representation, or picture, of familiar parts of your world, such as your neighborhood. (see Images and Cognitive Maps)
 - b.* Reconstructive memory is the process of filling the gaps in our memories with information that has been stored in long-term memory.
 - c.* There is no such thing as directional bias with regard to cognitive maps.
 - d.* *a* is the answer.
4. *b* is the answer. (see Propositions)
 - a.* Propositions are made up of words. (You may be thinking of phonemes and morphemes.)
 - c.* Propositions can be true or false.
 - d.* Mental models are made up of propositions, not the other way around. Propositions show the relationship between concepts or the relationship between a property or characteristic and a concept.
5. *c* is the answer. The concept is weapons, and a gun is the best example of a weapon. (see Concepts)
6. *c* is the answer. (see Formal Reasoning)
 - a.* A heuristic, not an algorithm, is a shortcut to the solution of a problem.
 - b.* An algorithm always produces a correct answer.
 - d.* An algorithm is not subject to bias.
7. *a* is the correct answer. These statements fit the definition of rules of logic by providing a formula for drawing valid conclusions about the world. (see Formal Reasoning)
 - b.* A counterfactual argument consists of currently untrue "what if" statements and does not apply here.
 - c.* The confirmation bias is an obstacle to problem solving that involves attending only to confirming information.
 - d.* Informal reasoning is used when the evidence is weighed to judge the credibility of a conclusion. It does not apply here.

8. *c* is the answer. In a heuristic strategy, the prince concludes that since Cinderella was dressed in finery and was at the ball, she must be the daughter of one of the kingdom's noblemen. When that strategy doesn't work, he uses an algorithmic strategy that, if followed, cannot fail to produce a correct answer if it exists. (see Informal Reasoning)
 - a. d.* You might have been thinking of schemas. There is no such thing as a schematic strategy.
 - b.* This choice is a reversal of the correct answer.
9. *d* is the answer. The con men look and act like the seniors' stereotype of trustworthy and hard-working young men. The seniors, therefore, decide that these men belong to that classification without processing more information about the situation. (see Informal Reasoning)
 - a.* Confirmation bias is a form of the anchoring heuristic.
 - b.* The anchoring heuristic is based on inadequate adjustments to first impressions as a result of new information. There is no comparison to new information here; the problem is jumping to a conclusion based only on the first impression.
 - c.* The availability heuristic involves judging how true a hypothesis is by how easily it or examples of it come to mind. If the question had included a statement that a neighbor had just had roof repairs done, the idea that roof repairs were needed might be judged more likely to be true because it would easily come to mind.
10. *a* is the answer. Jamila created an analogy for the problem of remembering how an action potential works. (see Strategies for Problem Solving)
 - b.* Decomposition is breaking apart a problem into subproblems and working on each.
 - c.* Ignoring negative evidence is an obstacle to problem solving.
 - d.* A script is a description of how you expect an event to go.
11. *d* is the answer. Many objects designed for a particular purpose can be used to solve other types of problems. However, when people can think of an object as serving only its intended purpose, they are victims of functional fixedness. (see Obstacles to Problem Solving)
 - a.* A mental set causes people to use old solutions to solve new problems instead of looking for simpler solutions.
 - b.* Confirmation bias occurs when people look only at information that will confirm a hypothesis.
 - c.* Ignoring negative evidence means that people do not consider the lack of symptoms when testing a hypothesis.
12. *d* is the answer. Getting stuck in one way of solving a problem is a mental set. (see Obstacles to Problem Solving)
 - a.* An algorithm is a formal reasoning procedure that always results in a correct answer.
 - b.* Functional fixedness is being unable to think of a novel use for an object.
 - c.* A mental model is a description of how something works.
13. *c* is the answer. In incubation, the problem is set aside for awhile. (see Strategies for Problem Solving)
 - a.* Deep structure is the meaning of a sentence.
 - b.* Expert systems are computer programs that are capable of solving problems in a specific area.
 - d.* Prototypes are the most typical example of a natural concept.
14. *a.* is the answer. The gambler's fallacy is the belief that events in a random process will correct themselves—will configure themselves to fit some purpose. Raymond figured that somehow the lottery machine would know that he had won and would not give him any more winning numbers. (see Biases and Flaws in Decision Making)
 - b.* People with loss aversion usually feel worse about losing an amount of money than they would feel good about gaining the same amount.
 - c.* Ignoring negative evidence is the practice of overlooking absent symptoms that might eliminate a hypothesis.

- d.* People with a confirmation bias are likely to ignore information that is inconsistent with their hypothesis.
15. *b* is the answer. The utility of a choice refers to its personal, subjective value to the decision maker. (see Evaluating Options)
- a.* The likelihood of a choice being the outcome deals more with expected value, which takes into account the probability of an outcome and its perceived benefits and costs.
- c.* The perception of risk relates to the probability of an outcome.
- d.* *b* is the answer.
16. *b* is the answer. Deep structure is the underlying meaning of a string of words. (see The Elements of Language)
- a.* Surface structure is the sequence of the words.
- c.* The syntax of the sentence is the set of rules that govern the way the words are strung together.
- d.* Deep structure refers to the meaning of a sentence, not to its complexity.
17. *b* is the answer. The sequence of activities Juan usually followed was disrupted, interfering with his perception of time. (see Schemas, Scripts, and Mental Models)
- a.* Schemas are knowledge structures. They are categories containing *all* of our knowledge about particular concepts, not just the specific series of events described in this question. This is not the *best* answer.
- c.* A mental model is one's idea about how something works. Juan's ideas of Sunday were those pertaining to a chain of events. Juan would have a mental model of how his muscles worked together when he jogged.
- d.* An image is a visual mental representation. Juan could, for example, mentally picture Sunday mornings as stacks of hotcakes, sausages, and steaming coffee.
18. *c* is the answer. Semantics is the set of rules governing the meanings of words and sentences. The words no va have a particular meaning in Spanish, but this particular combination of letters has no meaning in English. (see The Elements of Language)
- a.* Syntax is a set of rules governing the way words are put together.
- b.* A language acquisition device is an innate ability to understand the regularities of speech and the fundamental relationships between words.
- d.* The surface structure is the sequence in which words are strung together.
19. *d* is the answer. (see Understanding Speech)
- a, b, c.* Each option is only one part of the contextual information that will influence the interpretation of a sentence.
20. *d* is the answer. Children who are raised in a bilingual environment before the end of the critical period seem to show enhanced performance in each language. There is also some evidence that those who have roughly equal mastery of two languages are superior to other children in cognitive flexibility, concept formation, and creativity. (see How Is Language Acquired?)
- a, b, c.* Only *d* is correct.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 1 that you answered correctly.

ANSWERS TO MULTIPLE-CHOICE QUESTIONS

Circle the question numbers you answered correctly.

Sample Quiz 2

1. *c* is the answer. Reaction time is the time elapsed between the stimulus presentation and an overt response. (see Measuring Information-Processing)

- a.* Perceiving a stimulus is only part of the activity that takes place between the presentation of a stimulus and the overt response to that stimulus.
 - b.* The overt reaction to a stimulus is only part of the activity that takes place between the presentation of a stimulus and the overt response to that stimulus.
 - d.* Mental chronometry is the timing of mental events. Making an overt response, which is one of the activities measured by reaction time, is not solely a mental event.
2. *c* is the answer. A cognitive map is a mental representation of a familiar setting. Because the setting is unfamiliar to Lianne, she is probably using an incorrect cognitive map. (see Images and Cognitive Maps)
 - a.* A proposition is the smallest unit of knowledge that can stand as an assertion. They describe the relations between concepts.
 - b.* A schema is a generalization about categories of objects, events, and people. This question does not describe anyone making generalizations.
 - d.* A script is a mental representation of a sequence of events. This question does not describe anyone with an expectancy for event sequencing.
3. *d* is the answer. Cliff will need more time to respond to the green light (the stimulus) since he is driving a stick shift for the first time, which requires a starting procedure different from that of an automatic. Also, the light turned green sooner than he expected, and unexpected stimuli lengthen reaction time. Finally, an increase in the complexity of the decision will lengthen reaction time. Cliff has more than the usual number of streets to choose from when the light turns green. (see Measuring Information-Processing)
4. *b* is the answer. (see Propositions)
 - a.* Schemas are collections of information about the world that influence how we remember and store information.
 - c.* Syllogisms are basic arguments that consist of two premises.
 - d.* Scripts contain knowledge about sequences of human activity.
5. *d* is the answer. (see Concepts)
 - a, b.* Both natural and artificial concepts provide a way to classify objects.
 - c.* Artificial concepts have rigid definitions. If an object doesn't meet all the specifications, then it is not part of that particular artificial concept. Natural concepts are fuzzy. For example, an ostrich is a bird even though it doesn't meet all the criteria for "bird"—that is, it can't fly.
6. *a* is the answer. Although his gain equaled his loss, Lance feels worse about losing his four quarters than about finding a dollar to replace them. (see Biases and Flaws in Decision Making)
 - b.* Gambler's fallacy is the notion that random events will somehow correct themselves. If Lance were wondering if it were a coincidence to find a replacement for his lost quarters, this idea might apply.
 - c.* Expected value is the total amount of benefit you could expect if you repeated a risky decision on several occasions. A negative expected value means you would lose in the long run. It does not apply here.
 - d.* Decomposition is a strategy for problem solving by breaking a large problem into workable pieces.
7. *c* is the answer. Mental models are clusters of propositions that represent people's understanding of how things (usually physical things) work. (see Schemas, Scripts, and Mental Models)
 - a.* Schemas serve as general representations of a large set of more specific examples that generate expectations of the world. Schemas are broader than mental models.
 - b.* Scripts are mental representations of what is supposed to happen during sequences of events, such as weddings or parties. Mental models are clusters of propositions about how things or objects work.
 - d.* A proposition is the smallest unit of knowledge that can stand alone. A mental model is made up of many propositions.

8. *b* is the answer. An algorithm will always produce the correct answer, which in this case is winning the game. However, Clinton and his uncle will be playing for a very long time. Clinton will have to evaluate the consequences of every possible move he can make each time it is his turn. (see Formal Reasoning)
 - a*. Algorithms always produce a correct answer.
 - c, d*. People usually ignore overall probabilities when using a representativeness heuristic. Clinton is using an algorithm, not a heuristic.
9. *a* is the answer. Cindy starts out being 100 percent sure that she will get a job. After reading the paper, she should realize that her chances are very slim. Instead she is still very sure; she is anchored in her hypothesis that she will get a job. (see Informal Reasoning)
 - b*. People use the availability heuristic when they judge the probability of an event by how easily examples of that event come to mind. If Cindy had thought of all her many friends who had gotten jobs in the city, this would have been the correct answer.
 - c*. If Cindy were using the representativeness heuristic, she would have focused on the representative information (the paper) instead of her original estimate.
 - d*. There is no such thing as the base-rate information heuristic. (You may be thinking of the representativeness heuristic. Ignoring base-rate frequencies results in the use of this heuristic.)
10. *a* is the answer. Employees are judging the probability of terrorism based on the information that is most available to them. This bias is due to the availability heuristic. (see Informal Reasoning)
 - b*. Employees are not trying to determine whether an example is part of a class of objects as they would do when using the representativeness heuristic.
 - c*. Employees are not adjusting their hypothesis to match new information. They have made a decision about the degree of terrorist activity based on the information available to them.
 - d*. Only *a* is the answer.
11. *b* is the answer. Expert systems are computer programs that solve problems in very narrowly defined fields. The narrow definitions reflect the difficulty of putting all aspects of the reasoning of human experts into computer code. (see Problem Solving by Computer)
 - a*. This is not a major problem with expert systems. All complex computer programs are difficult to set up.
 - c*. This is a true statement about a group of human experts, but this question deals with expert systems.
 - d*. Making analogies is beyond the grasp of current expert systems.
12. *a* is the answer. The representativeness heuristic leads us to look at an example and compare it to a larger class of items. We focus on the similar appearances of the example and the larger class of items, ignoring information on how often the larger class of items occurs (overall probability). (see Informal Reasoning)
 - b*. The anchoring heuristic causes us to give improper weight to contradictory evidence in making a decision.
 - c, d*. The availability heuristic causes us to focus on the solutions that are most easily brought to mind and that are therefore most familiar. These are usually the hypotheses that have occurred most frequently in the past.
13. *b* is the answer. Mike wants to start with what the product has to do (an end point) and work backward to the solution of what the product will be. Cal wants to use an analogy: employing the same techniques that other companies employ in trying to solve the same kind of problem. (see Strategies for Problem Solving)
 - a*. Cal, not Mike, wants to employ an analogy by looking at other companies' solutions to the same problem. Decomposition is breaking a problem into its subparts.
 - c*. Mike is trying to develop his own strategy, not use a strategy that has worked for anyone else facing a similar problem.
 - d*. Mike is not letting the problem incubate by laying it aside for awhile.

14. *a* is the answer. Winnie has a hypothesis that Nelson is very smart. She takes into consideration only the evidence that supports her hypothesis and ignores evidence that Nelson is only average. (see Obstacles to Problem Solving)
 - b*. Winnie is testing a hypothesis, not trying to find a solution involving the use of an object.
 - c*. A mental set means using the solutions to old problems to try to solve new ones. Winnie is not using old solutions to test her hypothesis about Nelson's intelligence.
 - d*. Decomposition is a way to simplify problem solving by breaking a problem into smaller subproblems. Winnie is not engaged in this activity.
15. *a* is the answer. If Emmeline had thought of the hypodermics as being useful only for giving injections, she would have experienced functional fixedness. Instead, she used them for something other than their traditional function and solved her problem. (see Obstacles to Problem Solving)
 - b, d*. Confirmation bias occurs because people always try to confirm, rather than refute, their hypotheses. Emmeline is not testing a hypothesis, so neither of these alternatives is correct.
 - c*. People ignore negative evidence when looking for explanations of some event. Emmeline is not looking for an explanation but, rather, for a way to solve a problem.
16. *d* is the answer. Random events are independent of each other. For example, the result of the flip of a coin, whether for the first, second, third, or sixtieth time, is independent of the results of the previous flips. Each time the coin is flipped, there is a fifty-fifty chance of seeing heads. Gambler's fallacy occurs when someone thinks that because many heads have turned up, tails are soon due to appear. (see Biases and Flaws in Decision Making)
 - a, b, c*. Incorrectly estimating the probability of events is a bias in perception of probability, but neither this nor overconfidence in one's own predictions can be described as the gambler's fallacy.
17. *a* is the answer. The sentence has two meanings. The police are probably trying to catch jaywalkers, but it sounds as if they could be running them down with a vehicle! (see The Elements of Language)
 - b*. The sentence only has one surface structure, since that is the string of words.
 - c*. More than two morphemes make up the sentence. For example, campus, police, and start are all morphemes.
 - d*. More than two phonemes make up the sentence. For example, campus has six: c, a, m, p, u, and s.
18. *a* is the answer. Phonemes (sounds that affect the meaning of a word) make up morphemes (the smallest units of meaning in a language), which make up words. (see The Elements of Language)
19. *a* is the answer. The words a and the, as well as the ly and ed suffixes, make it easier for us to chunk the nonsense syllables in short-term memory, because of the similarity to English usage. The sentence also has syntax similar to English. (see The Elements of Language)
 - b*. There are no words or suffixes that help us chunk information in the second sentence. It is more difficult to remember, even though it is shorter than the first sentence.
 - c*. If one sentence is easier than the other, then both cannot be equally easy.
 - d*. The answer can be determined.
20. *b* is the answer. Many cases support the idea that a critical period exists for language development. The wild man was found when he was in his twenties and was past the critical period for language development. Therefore, he should not have been able to learn any language. (see How Is Language Acquired?)
 - a*. The language acquisition device Chomsky proposed is innate.
 - c*. When people learn a second language after the age of twelve to fifteen, they usually cannot speak with a flawless accent.
 - d*. Only *b* is the answer.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 2 that you answered correctly.

For each question you answered correctly, circle its number. (Quiz 1 numbers are not shaded; Quiz 2 numbers are shaded.) Are there patterns in the types of questions or the topics you got wrong that could direct your further study? Did you improve from Quiz 1 to Quiz 2?

CHAPTER 9

Consciousness

MULTIPLE-CHOICE QUESTIONS

Sample Quiz 1

1. Kelly and Juanita are having an argument. Kelly believes that consciousness is separate from the mind, while Juanita believes that consciousness and the mind are the same thing. Kelly believes in _____, and Juanita believes in _____.
 - a. materialism; dualism
 - b. dualism; materialism
 - c. PDP view; materialism
 - d. dualism; PDP view
2. Thad needs to track his blood-sugar level to keep his diabetes under control. Because blood-sugar level is at the _____ level of consciousness, he must use a blood test to check it.
 - a. nonconscious
 - b. unconscious
 - c. subconscious
 - d. preconscious
3. According to the concept of priming, which of the following is most likely to be the result of flashing a happy face [;>)] on a computer monitor too briefly for a viewer to notice?
 - a. There can be no effect if the viewer is unaware of the event.
 - b. The viewer will recognize the word *good* more quickly than *gourd* on a test a few seconds later.
 - c. There will be faster recognition of related words if the viewer is in a state of altered consciousness.
 - d. With repeated exposure, the viewer will develop feelings of euphoria, or extreme happiness.
4. A man with brain damage learns how to play golf, but when asked about his game, he has no conscious recollection that he has ever played golf in his life. This man appears to be suffering from
 - a. prosopagnosia.
 - b. anterograde amnesia.
 - c. an altered state.
 - d. posthypnotic amnesia.
5. Lisa can never seem to remember to take off her watch before she steps into the shower. This is probably because the sensation of the watch on her arm occurs at the _____ level.
 - a. nonconscious
 - b. preconscious
 - c. subconscious
 - d. unconscious
6. Slowed brain waves, deep breathing, a calm heart beat, and low blood pressure are prime indicators of
 - a. REM sleep.
 - b. hypnosis.
 - c. slow-wave sleep.
 - d. lucid dreaming.

7. EEG readings show different types of brain waves. Alpha waves indicate _____ and delta waves indicate _____.
- alertness; relaxation
 - alertness; deep sleep
 - relaxation; deep sleep
 - deep sleep; alertness
8. Most of a night's dreams occur during which stage of sleep?
- REM
 - Stage 4
 - Stage 2
 - About equally in all stages
9. Sleep apnea refers to
- vivid recurrent nightmares.
 - breathing problems during sleep.
 - excessive daytime sleepiness.
 - sudden sleep attacks.
10. REM sleep is most prevalent during
- infancy.
 - puberty.
 - young adulthood.
 - old age.
11. Michael Jordan has just flown back to Chicago from a golf game halfway around the world, and he is concerned about jet lag. What is the *most* effective thing he can do to reset his biological clock?
- Get as much sleep as possible after arriving
 - Sleep as little as possible after arriving
 - Spend as much time as possible outdoors after arriving
 - Take a sleeping pill to suppress REM sleep
12. Which of the following is *not* a current theory of why we dream?
- Dreams are the brain's attempt to make sense of meaningless stimulation during sleep.
 - We dream to satisfy unconscious urges.
 - Dreaming allows us to solidify information that has survival value.
 - Dreaming reduces our level of mental activity, heart rate, and blood pressure.
13. Khalid's therapist suggests that they use hypnosis to help him to quit smoking. During hypnosis the therapist tells Khalid that his next sight of a cigarette will make him feel nauseated. The therapist most likely is using _____ to help Khalid.
- age regression
 - posthypnotic amnesia
 - posthypnotic suggestion
 - reduced planfulness
14. Herman was dreaming of competing in the Boston Marathon. He didn't like how he was progressing, so he changed his position in the race. Herman was most likely
- hypnotized.
 - meditating.
 - experiencing lucid dreaming.
 - under the influence of psychoactive drugs.
15. If Eli is pretending that he is on a Caribbean beach, it is only because the situation provided him with a socially acceptable reason for seeing things that do not exist. This statement supports the _____ theory of hypnosis.
- dissociation
 - lucid
 - role
 - state

16. Norman has found himself a quiet spot, settled into a comfortable position, focused on the sound of his breathing, and assumed a passive attitude. He is about to
 - a. start meditating.
 - b. develop awareness of his nonconscious.
 - c. go to sleep.
 - d. start daydreaming.
17. Tolerance is
 - a. a need for larger and larger amounts of a drug to achieve the same effect.
 - b. a physical need for a drug.
 - c. dependence on a drug in order to function.
 - d. a drug buildup that prevents overdosing.
18. Abel's endorphin receptors were activated by the drug he took to reduce the pain from his broken arm. Therefore, the drug can be described as a(n)
 - a. agonist.
 - b. antagonist.
 - c. hypnagogic.
 - d. psychedelic.
19. The drug Abel took is most likely a(n)
 - a. depressant.
 - b. opiate.
 - c. hallucinogen.
 - d. stimulant.
20. Which of the following is true about the consumption of alcohol?
 - a. Eating prior to excessive drinking will prevent you from getting drunk.
 - b. It is impossible to overdose on alcohol.
 - c. Alcohol is a stimulant.
 - d. Alcohol can cause memory problems, poor motor coordination, and reduced inhibitions.

Total Correct (See answer key) _____

Sample Quiz 2

Use this quiz to reassess your learning after taking Quiz 1 and reviewing the chapter.

1. A person who agreed with the approach to the mind-body problem known as _____ would most likely believe that brain surgery would *not* affect a person's conscious mind.
 - a. Cartesian theater
 - b. dualism
 - c. materialism
 - d. PDP view
2. Following brain damage, Miranda is back to normal awareness in all respects except one: She cannot recognize faces, even those of her family. But when her doctors ask her to listen to voices, she can accurately discern those of her family members. Miranda's brain damage has caused
 - a. anterograde amnesia.
 - b. an altered state of consciousness.
 - c. implicit memories.
 - d. prosopagnosia.
3. Material that can be easily brought into consciousness is at the _____ level.
 - a. nonconscious
 - b. preconscious
 - c. subconscious
 - d. unconscious

4. Researchers primed positive expectations about the effects of alcohol in one of two groups of participants. The primed group was exposed to positive alcohol-related adjectives; the other group was exposed to neutral adjectives. Later both groups were given an opportunity to drink what they thought was an alcoholic drink (really nonalcoholic beer) as part of a "nonrelated" taste-rating study. What difference will researchers probably see between the two groups?
 - a. There will be no difference.
 - b. The participants who were primed will drink more than those who were not.
 - c. The participants who were primed will drink less than those who were not.
 - d. The participants who were primed will realize that the drinks did not contain alcohol.
5. Which of the following is the best example of a process operating at the nonconscious level?
 - a. Alice names all her teachers from kindergarten to the present.
 - b. Juan accidentally calls his sister "creepy" instead of "sleepy" because he dislikes her, although he is not consciously aware of it.
 - c. Chris now likes country music but doesn't realize that it's due to hearing it at work.
 - d. Derek uses biofeedback to help him control his blood pressure.
6. Which of the following statements about hypnosis is *true*?
 - a. Memories of hypnotized individuals may be less accurate than those of nonhypnotized individuals.
 - b. Anyone can be hypnotized.
 - c. Hypnosis is actually a stage of sleep.
 - d. There is no such thing as posthypnotic suggestion.
7. Altered states of consciousness are characterized by
 - a. increased reality testing.
 - b. changes in perception.
 - c. increased self-control.
 - d. planfulness.
8. If you have no circadian rhythms, you probably
 - a. cannot dance.
 - b. are dead.
 - c. cannot sleep.
 - d. are overly sensitive to norepinephrine.
9. Snookers the cat has decided that he wants a snack. However, his owner is taking a nap. Despite several minutes of tap-dancing on his owner's face, Snookers cannot wake her up. The cat's owner has most likely been asleep for
 - a. no more than five minutes.
 - b. no more than ten minutes.
 - c. at least thirty minutes.
 - d. This cannot be determined.
10. Delta just awakened from a very strange dream of a faceless man chasing her with a knife. The dream became very scary, but because it took place in REM sleep, she often had the feeling that she couldn't move or scream. Delta's dream would be classified as a
 - a. REM behavior disorder.
 - b. narcoleptic vision.
 - c. nightmare.
 - d. night terror.
11. Ruby has had a terrible evening. Just as her boyfriend, Kato, started to propose to her, he fell asleep. Ruby would feel better if she knew that Kato has
 - a. hypersomnia.
 - b. narcolepsy.
 - c. insomnia.
 - d. night terrors.

12. Which of the following people would most likely have the greatest amount of REM sleep?
- A person who goes to bed and gets up at exactly the same time each day
 - A person on vacation
 - A student who has been studying constantly for three days and three nights
 - A person with REM behavior disorder
13. Hypnosis has been used to reduce
- nausea due to chemotherapy.
 - surgical bleeding.
 - pain.
 - All of the above.
14. An example of a successful posthypnotic suggestion to Brendan is
- Brendan believes during hypnosis that he is unable to see.
 - Brendan is instructed during hypnosis to smile whenever anyone says *France*, and he does this when he is no longer hypnotized.
 - Brendan cannot remember what happened while he was hypnotized.
 - telling Brendan while he is no longer hypnotized that his pants are ripped and he checks them.
15. Brendan believes during hypnosis that he cannot see. Later, Brendan tells you that he felt like he was sharing control over his actions with the hypnotist. But also it was as if his ability to see was not part of him while he was hypnotized. Brendan's description of his experience agrees most with the _____ theory of hypnosis.
- dissociation
 - lucid
 - role
 - state
16. A mantra is
- a person trained in meditation.
 - a soothing word or phrase.
 - the position a person assumes when meditating.
 - a special form of meditation.
17. A molecule that fits into a receptor and blocks neurotransmitters from binding is a(n)
- agonist.
 - antagonist.
 - placebo.
 - cytoblocker.
18. Schizophrenia is a disease that may involve overactivity of the neurotransmitter dopamine. If this is so, then it would be important for drug treatments of schizophrenia to *exclude* dopamine
- agonists.
 - antagonists.
 - stimulants.
 - depressants.
19. Which of the following is *not* an opiate?
- Cocaine
 - Heroin
 - Morphine
 - Opium
20. During Cleo's sixteenth birthday party, the rumor spread that someone had spiked the punch (added alcohol to it). This was not the case, but
- those who believed the rumor became intoxicated when they drank the punch.
 - everyone who drank the punch became intoxicated.
 - no one who drank the punch became intoxicated.
 - those who heard the rumor became intoxicated when they drank the punch.
- Total Correct (See answer key) _____

ANSWERS TO MULTIPLE-CHOICE QUESTIONS

Circle the question numbers you answered correctly.

Sample Quiz 1

1. *b* is the answer. (see Analyzing Consciousness)
 - a.* Materialists believe that consciousness and the mind are the same thing, whereas dualists believe that consciousness is separate from the mind.
 - c.* A PDP view of consciousness holds that conscious experience is made up of parallel streams of information.
 - d.* Juanita may take a PDP view of consciousness, but this doesn't address her belief that the mind and consciousness are the same thing.
2. *a* is the answer. Blood sugar is at the nonconscious level, so Thad cannot become directly aware of it without a physical test. (see Levels of Consciousness)
 - b.* Unconscious mental activity cannot be easily brought to conscious awareness. Bodily processes below conscious awareness are categorized as being nonconscious.
 - c.* Subconscious is a synonym for unconscious.
 - d.* Preconscious activities can easily be brought to conscious awareness.
3. *b* is the answer. People tend to respond more quickly or more accurately to categories activated by previously seen stimuli processed outside of conscious awareness. (see Mental Processing Without Awareness)
 - a.* The priming effect, that of unconscious processing, has been demonstrated in numerous studies.
 - c.* Priming deals with unconscious processing, not with altered states of consciousness.
 - d.* There is no evidence that priming can lead to such extreme feelings.
4. *b* is the answer. Although people with anterograde amnesia have no memory of new information, they can learn new skills. (see The Neuropsychology of Consciousness)
 - a.* Prosopagnosia is the inability to recognize faces.
 - c.* An altered state of consciousness is a noticeable change from normal conscious functioning. This man just can't remember his newly acquired skills.
 - d.* Posthypnotic amnesia is lack of recall of being hypnotized.
5. *b* is the answer. Physical sensations and memories that we can easily access are at the preconscious level of activity. When Lisa stepped into the shower, the sensation of her watch on her arm was at the preconscious level of activity. (see Levels of Consciousness)
 - a.* Nonconscious activities are those that cannot reach consciousness. Lisa did feel the watch on her arm, even if she was a bit late in doing so.
 - c.* Subconscious activity cannot be easily brought into consciousness. The feeling of water between watch and skin is very easy to bring into consciousness.
 - d.* Unconscious activity cannot be easily brought into consciousness. The unconscious is the level to which Freudians suggest our socially unacceptable desires, impulses, and wishes are banished.
6. *c* is the answer. These are all indicators of slow-wave sleep. (see Stages of Sleep)
 - a.* REM sleep is active sleep, much like the waking state of consciousness.
 - b.* Hypnosis has characteristics similar to the waking state of consciousness.
 - d.* In lucid dreaming, individuals are asleep but are aware that they are dreaming. These features are not the prime indicators of lucid dreaming.

7. *c* is the answer. An EEG reading for a relaxed person with closed eyes shows alpha waves, and that of someone in deep sleep shows delta waves. (see Stages of Sleep)
a, b, d. Only *c* is correct.
8. *a* is the answer. Most dreams occur in REM sleep, although dreams can occur in other stages of sleep. (p. 299)
b, c. Dreams can occur in other stages of sleep, but most occur in REM sleep.
d. Dreams do not occur equally in all stages of sleep.
9. *b* is the answer. People suffering from sleep apnea stop breathing hundreds of times each night, waking up each time long enough to resume breathing. (see Stages of Sleep)
a. Recurrent nightmares are nightmares. They have nothing to do with breathing difficulties unless that is the subject of the nightmare.
c. Excessive daytime sleepiness can be the result of insomnia, the inability to sleep at night.
d. Sudden sleep attacks are a prime feature of narcolepsy.
10. *a* is the answer. An average infant sleeps 16 hours a day; about 8 hours of that is spent in REM sleep. (see Why Do People Sleep?)
b, c, d. As people get older, they spend less and less time asleep. Most of the loss is a decrease in REM sleep.
11. *c* is the answer. Michael Jordan needs to readjust to altered light-dark cycles, and staying in the natural light will be the fastest way to do so. (see Why Do People Sleep?)
a. He doesn't need more sleep. He needs to adjust to the light-dark cycles of Chicago again. Sleeping may make his jet lag worse if it is daytime in Chicago.
b. He doesn't need less sleep. He needs to adjust to the light-dark cycles of Chicago again. Not sleeping may make his jet lag worse if it is the middle of the night in Chicago.
d. REM sleep is not a primary factor in jet lag. Altered light-dark cycles are the problem.
12. *d* is the answer. Most dreams occur during REM sleep when our mental activity, heart rate, and blood pressure are similar to those of a person who is awake. (see Dreams and Dreaming)
a, b, c. These are all possible explanations of why people dream.
13. *c* is the answer. The therapist is giving a suggestion during hypnosis that will influence Khalid after he is no longer hypnotized. (see Experiencing Hypnosis)
a. In age regression, the person seemingly returns to childhood in thoughts or actions while hypnotized.
b. Posthypnotic amnesia is a person's inability to remember what happened while he or she was hypnotized.
d. A characteristic of people who are hypnotized is reduced planfulness. Khalid may tend not to initiate actions while hypnotized, but the therapist is trying to change his later behavior; therefore, this is not the best answer.
14. *c* is the answer. In lucid dreaming, Herman is aware that he is dreaming and may be able to intentionally direct the dream content. (see Dreams and Dreaming)
a. If Herman were hypnotized, the hypnotist would control Herman's progress in the marathon.
b. If Herman were meditating, he would not be dreaming but would be trying to attain inner peace and tranquility.
d. Dreaming occurs during sleep. Although psychoactive drugs can lead to sleep, they also have many other effects. This is too general an answer for the question.
15. *c* is the answer. Eli is acting in accordance with the social role of being a hypnosis subject; therefore, he is not in a different state. (see Explaining Hypnosis)
a. The dissociation theory states that people will experience changes in mental processes if enough control is relinquished to the hypnotist.

- b.* This is not a theory of hypnosis. You may have been thinking of lucid dreaming.
 - d.* State theorists would argue that hypnosis causes an altered state of mental activity, not compliance with a social role.
16. *a* is the answer. Norman is about to start meditating. Finding a quiet spot, assuming a comfortable position, focusing on one thing, and taking a passive attitude are all elements of meditation methods. (see Linkages: Meditation, Health, and Stress)
- b.* The nonconscious is totally removed from conscious awareness. Without biofeedback training, Norman cannot become aware of it.
 - c.* Use of one attentional focus and a passive attitude is more likely to be a method of meditation than sleep inducement.
 - d.* Daydreaming does not necessarily require a quiet spot; nor does it require a focus.
17. *a* is the answer. (see The Varying Effects of Drugs)
- b.* When there is a physical need for a drug, the person is addicted or physically dependent. Physical dependence can lead to tolerance, but they are not the same phenomenon.
 - c.* Psychological dependence occurs when the drug user relies on a drug in order to function every day. Not taking the drug may cause psychological discomfort.
 - d.* No matter how long people use a drug, they can still overdose if the amount is large enough.
18. *a* is the answer. An agonist binds with a receptor and stimulates it as a usual neurotransmitter would. (see Psychopharmacology)
- b.* An antagonist blocks neurotransmitters from entering a receptor.
 - c.* Hypnagogic state is the transition from wakefulness into sleep, not a drug type.
 - d.* A psychedelic is another term for a hallucinogen.
19. *b* is the answer. Opiates relieve pain and cause sleep. (see Opiates)
- a.* A depressant reduces activity of the central nervous system but is not used for pain relief.
 - c.* Hallucinogens alter perceptions, but do not relieve pain.
 - d.* Stimulants increase activation and do not reduce pain.
20. *d* is the answer. (see Depressants)
- a.* Eating prior to drinking may slightly delay the absorption of alcohol and therefore delay its effects, but it does not prevent them from occurring.
 - b.* It is possible to overdose on alcohol. The alcohol first affects the frontal cortex, then the midbrain, and finally the hindbrain.
 - c.* Alcohol is a depressant, which inhibits central nervous system activity.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 1 that you answered correctly.

Sample Quiz 2

1. *b* is the answer. Dualism views the mind and brain as separate. Our consciousness can become aware of brain events but is not merely the sum of brain activity. (see Analyzing Consciousness)
- a.* The Cartesian theater view deals with the nature of consciousness, not the mind-body problem. It suggests that incoming information joins together to create one experience.
 - c.* Materialism views the mind and brain as one entity. Just as a piano's keys, strings, and sound board are structures that work together to create music, our brain cells create our consciousness. According to this view, therefore, a surgery that changes a person's brain would change a person's conscious mind.
 - d.* The PDP view deals with the nature of consciousness, not the mind-body problem. It suggests that information of various sorts can be processed independently and simultaneously.

2. *d* is the answer. Prosopagnosia is characterized by an inability to recognize faces. (see Mental Processing Without Awareness)
 - a*. Anterograde amnesia is the inability to form new memories.
 - b*. An altered state occurs when changes in mental processes are great enough that significant differences in functioning are noted. Miranda is in the waking state of consciousness in all respects except for her inability to recognize faces.
 - c*. Implicit memories (see Chapter 7) influence us without our awareness, but incoming information is not a memory.
3. *b* is the answer. Preconscious memories can be recalled easily. (see Levels of Consciousness)
 - a*. Nonconscious processes are those physiological activities that people cannot become directly aware of.
 - c*. Subconscious activity includes thought processes that cannot easily be brought into consciousness, such as priming and mere exposure. This label is used by those who disagree with Freud's theory about the unconscious.
 - d*. Unconscious processes are also not easily brought into consciousness. Freud suggested that socially unacceptable urges are kept in the unconscious.
4. *b* is the answer. Priming has been shown to influence attitudes and behaviors. Those who were primed by being exposed to positive alcohol-related adjectives will probably drink more than those who were exposed to neutral adjectives. (see Mental Processing Without Awareness)
 - a*. There probably will be a difference; the group that was primed will probably drink more.
 - c*. The priming will influence the group to drink more, not less.
 - d*. Priming would most likely not endow participants with the sensitivity to detect alcoholic from nonalcoholic beverages.
5. *d* is the answer. Nonconscious activity is not available to our conscious awareness. In biofeedback training, a machine would indicate Derek's blood pressure, but he could not feel it. (see Levels of Consciousness)
 - a*. Alice is using her conscious memories to name her teachers.
 - b*. Juan may have an unconscious dislike of his sister.
 - c*. Chris may be experiencing the mere-exposure effect, which occurs at the unconscious level of consciousness.
6. *a* is the answer. Memories of past events reported by hypnotized, age-regressed individuals are less accurate than those of nonhypnotized individuals. (see Experiencing Hypnosis)
 - b*. Not everyone can be hypnotized. About 10 percent of adults are very difficult or impossible to hypnotize.
 - c*. Brain waves of hypnotized individuals are very similar to the waking state of consciousness, not to a sleep state.
 - d*. Hypnotic effects can last for days through posthypnotic suggestions—instructions about behavior to take place after hypnosis has ended.
7. *b* is the answer. People in an altered state of consciousness experience a change in mental processes significant enough for others to notice. Perceptions are altered and inhibitions are weakened. (see States of Consciousness)
 - a*. Reality testing is decreased in individuals who are in altered states of consciousness.
 - c*. Self-control is decreased in altered states.
 - d*. Planfulness, the ability to initiate action on one's own, is decreased in altered states.
8. *b* is the answer. Circadian rhythms are the cycles of behavior and physiology that repeat about every twenty-four hours. If you didn't have them, your body would not function, and you would be dead. (see Why Do People Sleep?)

- a. It is not that kind of rhythm.
 - c. Without circadian rhythms, if you slept you would probably never wake because you would follow no light-dark cycles.
 - d. A certain amount of sensitivity to norepinephrine is needed for alertness. This has no direct connection to circadian rhythms, but it may concern REM sleep.
9. c is the answer. During stage 4, a very deep sleep that occurs about thirty minutes after falling asleep, it is difficult to rouse someone. (see Stages of Sleep)
- a. After five minutes the sleeper would be in stage 1 or just entering stage 2 (not deep sleep).
 - b. After ten minutes the sleeper would be in stage 2 or 3 (not deep sleep).
 - d. It can be determined. Snooker's owner is in a very deep sleep, and the timing of the first episode of stage 4 sleep can be determined from sleep-cycle research.
10. c is the answer. Nightmares are frightening dreams that take place during REM sleep. (see Sleep Disorders)
- a. REM behavior disorder is a sleep disorder characterized by lack of muscle paralysis during REM sleep. The fact that Delta couldn't move eliminates this option.
 - b. Narcolepsy is the abrupt switch from a waking state into REM sleep. Narcoleptic vision is not a term.
 - d. Night terrors occur during stage 4 sleep. They involve horrifying images that cause a person to become extremely frightened. The person may wake up with a scream and be difficult to soothe.
11. b is the answer. People who have narcolepsy often fall asleep in the middle of an active waking state. They immediately shift into REM sleep. Ruby would feel much better if she knew that Kato had fallen asleep because of narcolepsy, and not because he was bored with the thought of their engagement. (see Sleep Disorders)
- a. People with hypersomnia sleep longer than most people at night, feel tired during the day, and take one or more naps during the daytime. However, they do not fall asleep in the middle of an active waking state.
 - c. If Kato had insomnia, he would not be able to fall asleep at all.
 - d. Night terrors occur during stage 4. Ruby is worried about why Kato fell asleep, not about what happened while he was asleep.
12. c is the answer. When people go without REM sleep, they have more REM periods than usual when they finally do sleep. (see Why Do People Sleep?)
- a. People who go to sleep and get up at the same time every day will not have their REM periods interrupted. Therefore, their REM periods will not increase in number or length.
 - b. A person on vacation would probably not be doing anything to require more REM sleep.
 - d. People with REM behavior disorder spend plenty of time in REM sleep. However, they do not experience muscle paralysis typical during REM sleep.
13. d is the answer. Hypnosis has been used to help people reduce nausea from chemotherapy, surgical bleeding, and pain: (see Applications of Hypnosis)
- a, b, c. These are all uses of hypnosis, but not the only uses.
14. b is the answer. Posthypnotic suggestions are given during hypnosis but are followed after hypnosis. (see Experiencing Hypnosis)
- a. Brendan may believe he is unable to see during hypnosis due to reduced reality testing. This is not posthypnotic because it occurs during hypnosis.
 - c. Not remembering what occurred while under hypnosis is posthypnotic amnesia.
 - d. This sounds like a joke that could work on anyone—hypnotized or not.
15. a is the answer. The dissociation theory states that people will experience changes in mental processes if enough control is relinquished to the hypnotist. (see Explaining Hypnosis)

- b.* This is not a theory of hypnosis. You may have been thinking of lucid dreaming.
 - c.* The role theory of hypnosis says that people are complying with a social role and are not in a different state.
 - d.* State theorists would argue that hypnosis causes an altered state of mental activity, but they do not include releasing control to the therapist and a dissociation of abilities (like sight) from central control.
16. *b* is the answer. (see Linkages: Meditation, Health, and Stress))
- a.* There is no special name for a person well versed in meditation.
 - c.* Many different types of positions have been used to meditate. Their only common characteristic is that they are comfortable.
 - d.* Several different techniques of meditation exist, but none of them is called a mantra.
17. *b* is the answer. Antagonists bind to a receptor but do not trigger action potentials. (see Psychopharmacology)
- a.* An agonist binds with a receptor but activates it as the neurotransmitter would.
 - c.* A placebo is not a molecule.
 - d.* Cyto blocker is a made-up name. There is no such thing.
18. *a* is the answer. Agonists are drugs that mimic the effects of neurotransmitters. If a person with schizophrenia has too much dopamine activity already, he or she does not need more. (see Psychopharmacology)
- b.* The drug that would help a person with schizophrenia would be a dopamine antagonist, one that would prevent dopamine activity.
 - c.* *Stimulants* is the name for a general class of drugs that increase behavioral and mental activity. Stimulants do not apply specifically to the effect of dopamine in schizophrenia.
 - d.* *Depressants* is the name for a general class of drugs that reduce central nervous system activity. Depressants do not apply specifically to the effect of dopamine in schizophrenia.
19. *a* is the answer. Cocaine is a stimulant. (see Stimulants)
- b, c, d.* Heroin, morphine, and opium are all opiates.
20. *a* is the answer. The drug itself does not necessarily have to be present to alter peoples' behavior. Learned expectations also play a role. So those who believed there was alcohol in the punch would expect to be affected by it and would behave accordingly. (see The Varying Effects of Drugs)
- b.* Only those who believed alcohol was in the punch would expect to become drunk.
 - c.* Learned expectations will influence those who think the punch is spiked.
 - d.* Again, only those who believed the rumor would expect to become drunk. Merely hearing the rumor would not affect behavior.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 2 that you answered correctly.

For each question you answered correctly, circle its number. (Quiz 1 numbers are not shaded; Quiz 2 numbers are shaded.) Are there patterns in the types of questions or the topics you got wrong that could direct your further study? Did you improve from Quiz 1 to Quiz 2?

CHAPTER 10

Cognitive Abilities

MULTIPLE-CHOICE QUESTIONS

Sample Quiz 1

1. Which of the following tests was first to have verbal and performance subscales?
 - a. ACT
 - b. Wechsler's Adult Intelligence Scale-III
 - c. The Stanford-Binet
 - d. The Binet
2. An average man has taken a modern intelligence test. His IQ score is most likely
 - a. 100.
 - b. 90.
 - c. the result of his mental age divided by his chronological age multiplied by 100.
 - d. IQ scores are no longer used to rank individual mental ability.
3. Today, IQ scores are relative scores. This means that your IQ will tell you
 - a. your g.
 - b. how many primary mental abilities you possess.
 - c. how intelligent you are in comparison to other people your age.
 - d. how creative you are.
4. Lonnie wants to design a test that will accurately measure mathematics aptitude. According to the text, what characteristics should Lonnie's test have?
 - a. Standardized conditions
 - b. Qualitative descriptions
 - c. Written questions
 - d. All of the above
5. A test is reliable if it
 - a. measures what it is supposed to measure.
 - b. predicts a person's success in some field.
 - c. yields consistent and stable results.
 - d. None of the above
6. A newly developed intelligence test was given to the same group of people twice. The large positive correlation between the two scores was significant; therefore, the test has
 - a. test-retest reliability.
 - b. split-half reliability.
 - c. high construct validity.
 - d. low predictive validity.

7. Which of the following is true with respect to reliability and validity?
 - a. A reliable test is always valid.
 - b. A valid test must have a substantial level of reliability.
 - c. There is no relationship between reliability and validity.
 - d. Reliability and validity are the products of standardization procedures.
8. What factors explain the *inability* of an IQ test to perfectly predict academic performance?
 - a. Academic success is not wholly determined by intelligence.
 - b. IQ tests may be culturally biased.
 - c. IQ tests may measure factors other than intelligence that do not influence academic success.
 - d. All of the above could explain the imperfect correlation between IQ and academic performance.
9. Randy's students are very upset with him. He told them that he was going to give a quiz on the principles of learning, but instead he asked about the principles of memory. The students told him that his quiz had no _____ validity.
 - a. test-retest
 - b. predictive
 - c. content
 - d. criterion
10. Comparing someone's job success with test scores received prior to employment results in an assessment of _____ validity.
 - a. criterion
 - b. content
 - c. predictive
 - d. split-half
11. The green species has an average IQ score that is ten points higher than the purple species. Given this information, what is the most accurate statement about the intelligence of any one member of green and any one member of purple?
 - a. The green individual is smarter than the purple individual.
 - b. We cannot draw any conclusions about their intelligence.
 - c. There is no difference in their intelligence.
 - d. The purple individual is smarter than the green individual.
12. Janice has been given an assignment: She is to devise a way to test the validity of intelligence tests. Why is her task so difficult?
 - a. She can't find a group of people to give the same test to twice.
 - b. Some controversy still exists over the definition of intelligence.
 - c. Intelligence covers a narrow range of qualities and abilities, whereas most IQ tests test a broad range of abilities.
 - d. None of the above
13. Which of the following is true about how the interaction between heredity and environment affects intelligence?
 - a. A favorable environment can improve a child's performance, even if the inherited influences on that child's IQ are negative.
 - b. Inherited characteristics are fixed, but environmentally determined features are changeable.
 - c. The environment has very little impact on a person's intelligence.
 - d. Inherited characteristics have very little impact on a person's intelligence.
14. Devon is a ten-year-old from an inner-city culture. He is taking an IQ test that requires him to match patterns. Devon most probably
 - a. has mental retardation.
 - b. is taking a culture-fair test.
 - c. is taking a culture-free test.
 - d. is taking a mathematical achievement test.
15. According to Cattell, fluid intelligence
 - a. is the basic power of reasoning and problem solving.

- b. is one dimension of cognitive style.
 - c. involves specific knowledge gained from experience.
 - d. None of the above
16. An educator who takes an information-processing approach would look to which of the following to explain a student's poor performance on an aptitude test?
- a. The student's g-factor
 - b. The student's attentional skills
 - c. The student's IQ
 - d. The environment in which the student was raised
17. Chuck says that intelligence is a general characteristic, meaning that a person capable in one area is also capable in another area. Chuck believes that testing people will support his hypothesis; therefore, he has a(n) _____ approach to intelligence.
- a. information-processing
 - b. multiple intelligences
 - c. psychometric
 - d. triarchic
18. Betsy's teacher evaluated her personal and body-kinesthetic intelligence, because the teacher believes that those are important skills *not* measured by standard intelligence tests. Betsy's teacher has the _____ approach to intelligence.
- a. information-processing
 - b. multiple intelligences
 - c. psychometric
 - d. triarchic
19. Shlomo and Jaime are both twelve years old. They were given identical boxes and told to open them. Shlomo finds the latch and pushes it up, down, and then sideways. Even though he cannot get the latch to open, he persists in his efforts. Jaime realizes that the latch is not going to open the box, so he looks at it from many different angles, trying to find another way to open it. Shlomo is thinking _____, and Jaime is thinking _____.
- a. convergently; divergently
 - b. divergently; convergently
 - c. convergently; convergently
 - d. divergently; divergently
20. Mary Beth has an IQ of 105, but she cannot write a sentence without mixing up the letters in some words or mixing up the word order. Mary Beth most likely has _____.
- a. cognitive complexity.
 - b. dysphasia.
 - c. dysgraphia.
 - d. familial retardation.

Total Correct (See answer key) _____

Sample Quiz 2

Use this quiz to reassess your learning after taking Quiz 1 and reviewing the chapter.

1. The original mental abilities test created by Binet was designed to _____.
- a. assess intelligence in children.
 - b. determine which children would benefit from special education.
 - c. determine which immigrants should be allowed into the country.
 - d. determine the intelligence of army recruits.
2. The strongest evidence of the role of heredity in determining intelligence is provided by the fact that the IQ scores of _____.
- a. identical twins raised separately are more similar than those of fraternal twins raised together.
 - b. fraternal twins are more similar than those of ordinary siblings.
 - c. identical twins raised together are more similar than those of identical twins raised apart.

- d. unrelated children raised in different homes are less similar than those of unrelated children raised in the same home.
3. Which of the following would you *not* find on the performance scale of an intelligence test?
- Block design
 - Maze solving
 - Picture completion
 - Mathematical word problems
4. Which of the following could jeopardize the standardization of a test?
- Individual variations in how the instructions are read to test takers
 - Changes in the way the test is scored
 - Variations in the environment in which the test is taken
 - All of the above
5. Consuela is giving a test that she has devised to the same group of people twice. She is testing for
- reliability.
 - validity.
 - norms.
 - None of the above
6. Lola has written a test for her psychology class. She is not sure of the test's reliability, so she compares the scores on just the odd questions to the scores on just the even questions. Which method is she using to test for reliability?
- Test-retest
 - Alternate forms
 - Split half
 - Criterion forms
7. A test is valid if it
- measures what it is supposed to measure.
 - is standardized.
 - yields consistent and stable results.
 - None of the above
8. Joel believes that knowledge of introductory psychology material is positively related to future success on the GRE test. Joel uses his students' combined midterm and final exam scores (called "exam total") as his measure of introductory psychology knowledge. He correlates exam total with the later obtained GRE scores of his students. Joel is trying to determine if his introductory psychology "exam total" has
- criterion validity.
 - predictive validity.
 - content validity.
 - split-half reliability.
9. Joel shows his midterm and final exams to the other psychology instructors to find if the items fairly assess knowledge of introductory psychology material. By getting the other instructors' opinions, Joel is evaluating his tests'
- alternate-form reliability.
 - split-half reliability.
 - content validity.
 - criterion validity.
10. In the interpretation of the differences between group scores of intelligence, _____ should be considered.
- socioeconomic status
 - the range of scores within each group
 - the test-takers' level of motivation
 - all of the above

11. One factor that does *not* help explain why higher family income results in higher IQ scores for children is that
- the parents' jobs and status may be related to innate intelligence that is passed on to their children.
 - income affects experience and environment.
 - children of upper income families may have greater motivation to succeed and to excel academically.
 - upper-income families live in neighborhoods with a genetically similar population.
12. Following are questions from an intelligence test for adults. The instructions, test environment, and scoring are the same for all test-takers. What color is the sun? How many fingers are on each hand? How many biological mothers do you have? The weather in summer is usually _____. What's wrong with this test?
- This test has no reliability.
 - This test has no validity.
 - This test is not standardized.
 - What is wrong cannot be determined from the information given.
13. Ana has developed a new test for engineering students. She is delighted because people's scores on her new test correlate highly with their scores on other engineering tests used to successfully measure their skill in this area. This demonstrates that her test has _____ validity.
- alternate forms
 - predictive
 - content
 - criterion
14. Studying scores on intelligence tests in order to understand the structure of intelligence is using the _____ approach.
- psychometric
 - information-processing
 - triarchic
 - divergent-convergent
15. A month after Hank bought his first calculator, it stopped working. Although he has no experience with fixing calculators, he figures that it might have a power supply problem. Hank looks for a battery compartment, but there isn't one. Hank notices a tiny screw at each corner of the case, so he opens the case, finds the batteries inside, and replaces them. Hank fixed his calculator without having experience to guide him; therefore, he used mostly _____ intelligence.
- crystallized
 - fluid
 - intrapersonal
 - triarchic
16. White male college students in an advanced calculus course were randomly assigned to two groups. Group A was told they were participating in a study to determine why Asian males outperform all other groups in math-related tasks. Group B was told nothing. Both groups completed a math achievement test. According to the phenomenon known as stereotype threat, what will be the test results of the two groups?
- Group A will perform better than Group B.
 - Group A will perform worse than Group B.
 - Both groups will perform worse than expected.
 - The performance of the two groups will not differ.
17. Convergent thinking is
- typical of creative people.
 - characterized by thinking of many alternative solutions to a problem.
 - measured by intelligence tests.
 - All of the above

18. Corrina agrees with the multiple intelligences approach to mental abilities. *Unlike* people with any other approach, Corrina would be interested in hearing about a person's
- athletic ability.
 - attention level.
 - spatial visualization.
 - vocabulary.
19. Which of the following statements about people with mild mental retardation is *not* accurate?
- They perform certain mental operations more slowly than other people do.
 - They know fewer facts about the world than other people know.
 - They tend to forget information from working memory at a faster rate than other people do.
 - They are less able than others to use particular mental strategies that may be important in learning and problem solving.
20. If scientists ever capture an alien, they will want to check its creativity. Which of the following would be the best way to do that?
- See how fast it learns to speak English.
 - Administer a verbal scale of the Wechsler.
 - Administer a performance scale of the Wechsler.
 - Administer a test of divergent thinking.

Total Correct (See answer key) _____

ANSWERS TO MULTIPLE-CHOICE QUESTIONS

Circle the question numbers you answered correctly.

Sample Quiz 1

- b* is the answer. The WAIS-III was the first test to have verbal and performance subscales. (see A Brief History of Intelligence Tests)

 - c*. Both the Stanford-Binet and the ACT use subscales, but were not first to introduce their use.
 - There is no such test as The Binet.
- a* is the answer. The arbitrary number 100 is assigned to the average score obtained by people at a particular age level. Other IQ numbers reflect how much the scores deviate from the average. (see A Brief History of Intelligence Tests)

 - A score of 90 would indicate that the person scored below the age-group average.
 - This formula was the scored method used early in the twentieth century by Lewis Terman.
 - As long as there is testing for differential abilities, there will be scoring and ranking.
- c* is the answer. An IQ score tells how smart you are relative to other people your age. If your IQ is 100, then you are average with respect to others your age. A higher IQ means you scored higher than others your age. (see A Brief History of Intelligence Tests)

 - Spearman concluded that intelligence is a combination of general mental ability, *g*, and a group of special intelligences, *s*. Neither *g* nor *s* provide comparative information about IQ.
 - Thurstone suggested that intelligence is made of primary mental abilities. An IQ score may tell you about these abilities, but more important, the score tells about them relative to other people.
 - An IQ score will not tell you how creative you are. IQ scores are not highly correlated with creativity.
- a* is the answer. An advantage of using a test is that the administration, scoring, and interpretation are standardized. (see Measuring the Quality of Tests)

 - Quantifiable terms allow norms to be calculated. Qualitative descriptions would not be numerical.

- c. A test does not have to be written. Lonnie could have people listen to a problem and use tokens to show a number answer.
 - d. Only *a* is correct.
5. *c* is the answer. Reliable tests yield consistent and stable scores over time. (see Reliability)
- a. When a test measures what it is designed to measure, it has validity.
 - b. When a test can predict someone's success in a particular field, it has predictive validity.
 - d. *c* is the answer.
6. *a* is the answer. (see Reliability)
- b. Split-half reliability is checked by comparing answers on half of the items on a test to the other half.
 - c, d. Validity is not determined by administering the same test twice. Construct validity is based on a theory about the concept. Predictive validity compares scores on a test to a criterion later.
7. *b* is the answer. If a test is valid, it must be reliable. If a test produces scores that vary from one test occasion to another, there is no way that the test would correlate highly enough with a criterion to establish validity. (see Reliability)
- a. A test that is reliable is not necessarily valid.
 - c. There is a relationship between reliability and validity, while a reliable test yields the same results repeatedly. A valid test must have a substantial level of reliability.
 - d. If a test is valid, it measures what it is supposed to measure. This is not dependent on standardization procedures. Standardization does not guarantee validity.
8. *d* is the answer. Cultural bias, other factors affecting academic success, and the fact that IQ tests may measure factors other than intelligence (such as motivation) all contribute to the imperfect correlation between IQ scores and academic success. (see Validity)
9. *c* is the answer. The questions on the quiz did not assess the knowledge they were supposed to test. (see Validity)
- a. Test-retest is not a type of validity. It is a type of reliability.
 - b. Using a test to predict the ability to carry out some later endeavor successfully, such as a job or major in school, requires the test to have predictive validity.
 - d. The correlation of a test score with some other measure of the ability tested is the test's criterion validity.
10. *c* is the answer. A test score should predict the future performance of the test taker on the job. This is predictive validity. (see Validity)
- a. When test scores correlate highly with another measure of the ability tested, then the test has high construct validity.
 - b. If a test measures what it is supposed to measure, it has high content validity.
 - d. There is no such thing as split-half validity. (You may have been thinking of split-half reliability.)
11. *b* is the answer. A group score is an average of the scores of a large number of people; it says nothing about a particular individual. (see Group Differences in IQ Scores)
- a, c, d. A group average tells us nothing about individual members of a group.
12. *b* is the answer. It is very difficult to tell if a test is measuring what it is supposed to measure when the tester can't define what is supposed to be measured. (see Validity)
- a. This is an example of not being able to check test-retest reliability.
 - c. Intelligence covers a broad range of qualities and abilities, whereas most IQ tests test a narrow range of abilities.
 - d. *b* is the answer.
13. *a* is the answer. The quality of the environment can cause children's IQ scores to increase. (see IQ Scores as a Measure of Innate Ability)

- b.* The opposite is true: inherited characteristics are not necessarily fixed, and environmentally determined features are not necessarily changeable.
- c, d.* Neither of these statements is true. Both genetics and the environment have a large impact on the development of intelligence.
14. *b* is the answer. Devon is taking a test that does not rely heavily on education and verbal abilities. This test is attempting to measure intelligence instead of the effect of cultural advantages, such as an education. (see The Reliability and Validity of IQ Tests)
- a.* Many normal children—not just those with mental retardation—take IQ tests.
- c.* There is no such thing as a culture-free test.
- d.* Devon is being asked to match patterns, not to do mathematical tasks. Additionally, an achievement test measures what has already been learned: Devon is taking an IQ test, which attempts to measure intelligence, not knowledge.
15. *a* is the answer. Cattell argued that there are two types of g-factor: fluid intelligence and crystallized intelligence. Fluid intelligence is the basic power of reasoning and problem solving. It produces induction, deduction, reasoning, and understanding of relationships between different ideas. (see The Psychometric Approach)
- b.* Cognitive style is the manner or style of performing cognitive tasks. Cognitive complexity, field dependence versus independence, and impulsive versus reflective styles are all dimensions of cognitive style.
- c.* Crystallized intelligence involves the specific knowledge gained from past experiences as a result of applying fluid intelligence.
- d.* *a* is the answer.
16. *b* is the answer. Within the information-processing model, effective intellectual functioning is related to competence in basic mental processes. An educator would look at these skills to explain poor performance on an aptitude test. (see The Information-Processing Approach)
- a.* The analysis of a general intelligence, or *g*, centers on the correlations among various measures of mental abilities. The information-processing approach is not concerned with final scores, but with the various skills involved in achieving them.
- c.* Because this model focuses on attentional resources, speed of access to memory, and other processes of intelligent behavior, the product of that intelligence (one test score) would not explain poor performance on another measure.
- d.* Examining the influence of environmental factors on intelligence is not a component of the information-processing approach.
17. *c* is the answer. The psychometric approach looks for a general factor of intelligence by using tests. (see The Psychometric Approach)
- a.* The information-processing approach emphasizes the influence of attention skills and processes of sensation, perception, and memory.
- b.* Multiple intelligences is the approach emphasizing that people could have a high level of one ability (musical intelligence) and a low level of another (logical-mathematical intelligence).
- d.* The triarchic theory focuses on components and adaptation to the environment.
18. *b* is the answer. The multiple intelligences theory focuses on abilities not measured by standard IQ tests. It states that a person could be high in one type of intelligence and low in others. (see Multiple Intelligences)
- a.* The information-processing approach believes that attention, perception, and memory influence our level of intelligence.
- c.* The psychometric approach has an interest in more standard IQ testing. Verbal comprehension and numerical ability, for example, are important to the psychometric approach.
- d.* The triarchic theory focuses on components and adaptation to the environment.

19. *a* is the answer. Shlomo is thinking convergently, but Jaime, by imagining all the possible ways to open the box, is thinking divergently. (see Creativity)
b, *c*, and *d*. Only *a* is correct.
20. *c* is the answer. Mary Beth has trouble with writing that may be due to the learning disability dysgraphia. People with learning disabilities do not perform as well as their IQ test scores would suggest. (see Unusual Cognitive Ability)
a. Cognitive complexity assists people in thinking about many aspects of a problem.
b. Dysphasia is a learning disability in which people have trouble understanding spoken words or recalling the words needed for effective speech.
d. Familial retardation is usually mild and results from an interaction of genetic and environmental influences. Mary Beth is of average or slightly above-average intelligence; she does not have any form of retardation.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 1 that you answered correctly.

Sample Quiz 2

1. *b* is the answer. Binet's original test was designed to identify those children who would benefit from or need special instruction. (see A Brief History of Intelligence Tests)
a. Binet did not try to create an intelligence test. He only wanted to identify those children who would benefit from special instruction.
c, *d*. Psychologists in the United States revised Binet's test and used it to assess the intellectual capacity of immigrants and army recruits.
2. *a* is the answer. If the IQ scores of twins who have the same genes but are raised in different environments are more similar than the scores of twins with different genes who are raised in the same environment, we can conclude that the similarity of genes was also responsible for the similarity of IQ scores. (see IQ Scores as Measures of Innate Ability)
b. This is evidence for environmental influence. Fraternal twins and ordinary siblings both develop from separate eggs and thus have different genes. The scores of fraternal twins may be more similar because their environment may be more similar. They were born at approximately the same time and they share many experiences.
c, *d*. This is evidence for environmental influence. Children raised in the same environment will be more similar than children raised in different environments.
3. *d* is the answer. Although math skills in general do not require a great deal of language ability, mathematical word problems do. The test taker must be able to read, interpret, and set up the problem using language skills as well as mathematical reasoning in order to arrive at the solution. (see Intelligence Tests Today)
a, *b*, *c*. Block design, mazes, and picture completion are all problems that require no verbal skills.
4. *d* is the answer. Variations in administration, scoring, or the test-taking environment could jeopardize the standardization of a test. (see Measuring the Quality of IQ Tests)
5. *a* is the answer. A reliable test is one that gives stable and consistent answers. If a test is given twice and yields consistent results, it is considered reliable. (see Reliability)
b. Giving the same test twice is a test of reliability, not validity. To check validity, you must make sure that the content of the questions relates to the skills or knowledge being tested or that the test scores are correlated with scores on other tests relating to the same constructs or criteria.
c. Norms are descriptions of the frequency of particular scores. In order to test for this, the same test would have to be given to a very large number of people, not the same people twice.
d. *a* is the answer.
6. *c* is the answer. Comparing the scores on one half of a test to scores on the other half is the split-half method of testing reliability. (see Reliability)

- a. The test-retest method requires the same people to take the same test twice. Their scores on the first test should be very similar to those on the second test.
 - b. The alternate-forms method requires giving two different but equivalent forms of the test to the same people.
 - d. There is no such thing as the criterion-forms method.
- 7. a is the answer. (see Validity)
 - b. Standardization refers to the use of the same methods every time the test is given.
 - c. A reliable test yields consistent and stable scores over several test sessions.
 - d. a is the answer.
- 8. b is the answer. Predictive validity involves determining if the test in question predicts future criteria of interest. Joel is determining if his introductory psychology exam totals predict GRE performance. (see Validity)
 - a. Criterion validity is similar to predictive validity, but it does not involve actual prediction. Concurrent scores are correlated to determine if the test in question is related to other measures of the ability.
 - c. Content validity involves determining if your test measures the appropriate substantive content.
 - d. Split-half reliability involves determining if the test in question is internally consistent by correlating two separate but equivalent halves of the test.
- 9. c is the answer. Asking other psychology instructors about the items on his test will evaluate the content validity. (see Validity)
 - a, b. Alternate-form reliability and split-half reliability both involve comparing two sets of scores (two tests or two halves of a test, respectively). Joel is only asking for opinions.
 - d. Criterion validity is evaluated by comparing a new test to an accepted measure of the same construct.
- 10. d is the answer. Group scores can be affected by socioeconomic differences. Motivation of individual test-takers can affect scores. And if there is a difference in group means, the distributions of group scores may overlap. (see Group Differences in IQ Scores)
- 11. d is the answer. The ethnicity of a neighborhood has nothing to do with why high income leads to children with higher IQs. Lower-class communities have lower average IQs than are found in upper-class communities of the same ethnic make-up. Many high-income neighborhoods are populated by a variety of ethnic groups. (see Group Differences in IQ Scores)
 - a, b, c. All of these factors influence the relationship between IQ and socioeconomic status.
- 12. b is the answer. Most people could answer these questions. Therefore, this test will not tell you how people differ in intelligence. (see Validity)
 - a. This test is very reliable. You would give exactly the same answers every time you took it.
 - c. This test is standardized: it is administered and scored in exactly the same way every time for everyone.
 - d. What is wrong can be determined.
- 13. d is the answer. The correlation of a test score with some other measure of the ability tested evaluates the test's criterion validity. (see Validity)
 - a. When two alternate, but substantively equivalent, versions of a test are highly correlated, the test has alternate forms reliability. Alternate forms is not a type of validity.
 - b. Using a test to predict the ability to carry out some later endeavor successfully, such as a job or major in school, requires the test to have predictive validity.
 - c. When a test measures the knowledge "content" it is supposed to measure, the test has content validity.

14. *a* is the answer. Psychologists who seek to understand the structure of intelligence by examining the correlations among scores on IQ tests are following the psychometric approach. (see The Psychometric Approach)
- b.* The information-processing approach studies the mental processes underlying intelligent behavior, such as the speed of information transfer from short-term to long-term memory.
- c.* The triarchic approach involves specific knowledge components and metacomponents: the ability to know how to set up a problem in order to solve it.
- d.* There is no such thing as the divergent-convergent approach to studying intelligence.
15. *b* is the answer. Fluid intelligence is basic reasoning power. Hank knew little about calculators, but logically deduced that the batteries stored inside needed to be changed. (see The Psychometric Approach)
- a.* Crystallized intelligence is composed of specific knowledge. For example, vocabulary and trivia are part of crystallized intelligence.
- c.* Intrapersonal intelligence is part of Gardner's multiple intelligences theory. It relates to how well people understand themselves.
- d.* Triarchic theory, by Sternberg, may be what you were thinking of. It is not a type of intelligence.
16. *b* is the answer. Stereotype threat is the idea that priming of a stereotype about a group's lower ability in comparison to others will distract members of that group so that they may become anxious and fail to perform at the level of their ability. Group A received this priming. (see Linkages: Emotionality and the Measurement of Cognitive Abilities)
- a.* Group A, facing the stereotype threat, will be distracted by the overgeneralized comparison. Since their attention is diverted from the task, they will not perform as well as Group B, which had no such distraction.
- c, d.* Neither of these results would be predicted by stereotype threat.
17. *c* is the answer. Convergent thinking is the ability to apply rules of logic and general knowledge of the world in order to solve problems. IQ tests measure convergent thinking. (see Creativity)
- a.* Divergent thinking is characteristic of creative people.
- b.* Divergent thinking is characterized by thinking of many alternative solutions to a problem.
- d.* Only *c* is the answer.
18. *a* is the answer. According to the multiple intelligences approach, athletic ability is body-kinesthetic intelligence. (see Multiple Intelligences)
- b.* Attention level is important to an information-processing theorist.
- c.* Spatial intelligence is part of the multiple intelligences approach, but it is also measured by psychometric theorists.
- d.* Vocabulary is not part of the multiple intelligences approach. People with a psychometric approach are interested in language comprehension; therefore, it may be an interest of theirs.
19. *c* is the answer. People with mild mental retardation are just as proficient as others in recognizing simple stimuli, and they do not tend to forget information from working memory at a faster rate. (see Unusual Cognitive Ability)
- a.* People with mild mental retardation do perform certain mental operations more slowly.
- b.* People with mild mental retardation do tend to know fewer facts about the world.
- d.* People with mild mental retardation do have difficulty using some mental strategies that are important in learning and problem solving.
20. *d* is the answer. Tests of divergent thinking measure creativity. (see Creativity)
- a.* The ability to learn a new language is not correlated with creativity.
- b, c.* IQ scores do not correlate highly with creativity.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 2 that you answered correctly.

For each question you answered correctly, circle its number. (Quiz 1 numbers are not shaded; Quiz 2 numbers are shaded.) Are there patterns in the types of questions or the topics you got wrong that could direct your further study? Did you improve from Quiz 1 to Quiz 2?

CHAPTER 11

Motivation and Emotion

MULTIPLE-CHOICE QUESTIONS

Sample Quiz 1

1. Motivation is considered an intervening variable because
 - a. it is a stimulus that causes a response.
 - b. motives or needs are causes of behavior.
 - c. it helps explain the relationship between stimuli and responses.
 - d. motives or needs are responses to external stimuli.
2. Drive theory cannot explain which of the following behaviors?
 - a. Eating when hungry
 - b. Drinking when thirsty
 - c. Putting on warm clothes when cold
 - d. Exploring a new environment
3. Stewart desperately wants a job in the computer field. He has just finished an interview during which he was aggressive about his thoughts and ideas. An incentive theorist would say that Stewart
 - a. has a strong aggressive instinct.
 - b. thinks that being aggressive will land him the job.
 - c. has a very high optimal level of arousal.
 - d. is worried about having enough money to live on.
4. Which of the following is the best evidence that differences in what men and women look for in mates are more cultural than biological?
 - a. Men in the United States are more ambitious than men in Canada.
 - b. Most men look for an attractive mate.
 - c. Most women try to look younger.
 - d. Zulu women are expected to be physically strong, ambitious, and mature.
5. Dwayne enjoys spending quiet evenings at home, watching old movies. To best explain his motivation for this behavior using the arousal theory, we should say that Dwayne
 - a. is rewarded by his enjoyment of the movies.
 - b. has hectic, busy days and wants some peace and quiet in the evenings.
 - c. has an emotional need fulfilled by watching the movies.
 - d. has met his physiological needs and therefore can seek arousal.
6. Cholecystokinin is involved in the regulation of
 - a. eating.
 - b. thirst.
 - c. sex.
 - d. arousal.
7. Stefan is working a late-night shift in the emergency room. His next patient is a girl who is very dehydrated. Upon examination, Stefan finds that the girl's weight is normal but that she has nutritional imbalances and intestinal damage. Stefan's patient is probably suffering from
 - a. anorexia nervosa.
 - b. bulimia nervosa.
 - c. obesity.
 - d. None of the above
8. One survey of sexual behavior in the United States found that
 - a. single people report having the most frequent and satisfying sex.
 - b. people tend to be attracted to and have sex with many partners in their lifetime.
 - c. people in committed, monogamous relationships have the most frequent and satisfying sex.
 - d. most people have sex an average of three times a week.

9. Kate has a high need for achievement. Kate's parents most likely
 - a. encouraged her to try new challenges and rewarded her successes.
 - b. always got involved with her work and even helped her finish assignments.
 - c. told her to quit torturing herself and give up when things got tough.
 - d. did not praise Kate very much because they did not want her to become satisfied and quit trying new things.
10. According to Maslow, if you were shipwrecked on a desert island, which of the following would you most likely do first?
 - a. Look for dinner and fresh water
 - b. Look for inhabitants
 - c. Establish a form of self-government
 - d. Build a place to live
11. The first time military parachutists jumped out of a plane, some were so frightened that they involuntarily urinated on themselves. Once they landed safely, they felt relief and excitement. After repeated jumps, the initial fear response subsided and the feelings of euphoria intensified. Which theory of motivation best explains this behavior?
 - a. Arousal
 - b. Drive reduction
 - c. Incentive
 - d. Opponent-process
12. Jeff is unsure of what to do. A woman whom he doesn't like at all has invited him to go to a really great concert. She has offered to pay, but he still thinks she's egotistical and irritating. Jeff is experiencing a(n) _____ conflict.
 - a. approach-approach
 - b. approach-avoidance
 - c. avoidance-avoidance
 - d. multiple approach-avoidance
13. The Hanley brothers became addicted to a type of video game because a pleasure center in the brain was stimulated each time they scored. Eventually, the Hanleys played the game nearly constantly and simultaneously experienced a pleasurable emotion and a physiological reaction. This is most supportive of which of the following?
 - a. Schachter's modification of James's theory
 - b. Cannon's theory
 - c. James' theory
 - d. Arousal theory
14. Kurt, who is about to take a lie detector test, has sneakily put a tack in his shoe. Kurt should jam the tack into his toe to show an increase in physiological response after
 - a. questions about his alibi.
 - b. control questions.
 - c. relevant questions.
 - d. questions about his age, education, and income.
15. Matt is very interested in a woman he met at the gym. When would be the best time for him to approach her to talk?
 - a. As she is warming up before her workout
 - b. During her workout
 - c. When she is toweling off right after her workout
 - d. In the parking lot after a shower
16. When people are scared to do something, they are said to have cold feet. Fear really is associated with a decrease in blood flow to the feet and hands, which supports _____ theory of emotion.
 - a. Cannon's theory
 - b. James's theory
 - c. the incentive theory

- d. Schachter's cognitive modification
- 17. The people of Ifaluk, a tiny island in the Pacific, condemn the expression of happiness because it may interfere with carrying out one's duties. This is part of the Ifaluk's
 - a. extrinsic motivation.
 - b. emotion culture.
 - c. social referencing system.
 - d. pyramidal motor system.
- 18. Gloria went to the doctor for her usual antiallergy shots. The nurse mistakenly gave her a shot of epinephrine, which caused a great deal of physiological arousal. As Gloria sailed out of the office, she decided that she was feeling shaky from drinking too much caffeinated coffee. Her lack of emotion despite physiological arousal can be explained by which of the following?
 - a. Darwin's theory
 - b. James's theory
 - c. Schachter's cognitive modification
 - d. Cannon's theory
- 19. When Michele heard someone trying to open her car door while she was stopped at a light, she felt her heart race. A few seconds later, without consciously considering her situation, she knew her physical response was fear. Michele's experience supports which of the following?
 - a. The arousal theory
 - b. Cannon's theory
 - c. James's theory
 - d. Schachter's cognitive modification
- 20. Sam is unsure of the proper response to make to a comment from one of his friends, so he glances at Diane, his girlfriend, to see what her reaction is. He is using
 - a. facial feedback.
 - b. social referencing.
 - c. attribution.
 - d. transferred excitation.

Total Correct (See answer key) _____

Sample Quiz 2

Use this quiz to reassess your learning after taking Quiz 1 and reviewing the chapter.

- 1. Which of the following is the best illustration of motivation as an intervening variable?
 - a. A bell causes a rat to salivate.
 - b. When a person passes a candy machine, she doesn't get candy unless she is hungry.
 - c. A relative calls you "amazing" and a "genius."
 - d. A person tries to smile although he feels depressed.
- 2. Homeostasis is a key concept in which theory of motivation?
 - a. Instinct theory
 - b. Arousal theory
 - c. Incentive theory
 - d. Drive theory
- 3. Drew thinks that the concept of learning is vital to understanding motivation. Which of the following theories of motivation would he be least likely to agree with?
 - a. Arousal theory
 - b. Drive theory
 - c. Instinct theory
 - d. Incentive theory
- 4. Allison is a 25-year-old woman who is interested in a long-term romantic relationship. According to the evolutionary approach, to which of the following people would Allison most likely be attracted?
 - a. Susan, a 25-year-old graduate student nearing completion of her degree

- b. Tom, a 25-year-old artist who has a secretarial day job
 - c. Vic, a 33-year-old banker with a good salary and an interest in having children
 - d. Wally, an 18-year-old, good-looking waiter who likes movies, fast cars, and having fun at parties
5. Anorexia nervosa is characterized by
- a. eating more calories than are necessary for body maintenance.
 - b. self-starvation and weight loss.
 - c. overeating and self-induced vomiting.
 - d. None of the above
6. Jack was in training to lose enough weight to make a lighter class in wrestling. When his roommates invited him to join them for dinner at the Bavarian Buffet restaurant, Jack declined and ate alone at home. All else being equal and assuming it was the normal dinner hour, what may we suspect as the reason for Jack's refusal?
- a. He had lost his appetite.
 - b. He was afraid he would overeat.
 - c. He was afraid his nutritional balance would be thrown off course.
 - d. It would violate his food culture.
7. Liz was sweaty, uncomfortable, and unable to work because of the heat. Liz wants to buy an air conditioner to help her cool off; therefore, Liz is experiencing a(n) _____ drive.
- a. cognitive
 - b. emotional
 - c. primary
 - d. secondary
8. Keenan is an adult male; therefore, which of the following statements are true of him?
- a. He has no estrogens.
 - b. More progestins and estrogens than androgens circulate in his body.
 - c. More androgens than progestins and estrogens circulate in his body.
 - d. He has no androgens.
9. Julie, who has a high need for achievement, is trying to decide where to work. Which job should she take?
- a. Company 1: high pay, little responsibility, great boss
 - b. Company 2: low pay, lots of responsibility, mediocre boss
 - c. Company 3: medium pay, lots of responsibility, chances for advancement, demanding boss
 - d. Company 4: very high pay, easy work, not much chance for advancement, great boss
10. Marta claims that she will not be satisfied until she gets the respect she deserves for the job she does at work. According to Maslow's hierarchy of needs, Marta has
- a. given up her biological needs because she probably was unable to fulfill them.
 - b. probably been poor all of her life.
 - c. had her lower needs fulfilled to an acceptable degree.
 - d. not had her lower needs fulfilled to an acceptable degree.
11. The board of trustees could not understand why faculty morale was so low and why so many faculty members were accepting positions at other colleges. Which of the following probably had the *least* negative effect on employee motivation?
- a. An article in the local paper quoted some board members as saying that the faculty members were getting lazy.
 - b. Due to budgetary problems, the college canceled all raises for one year.
 - c. When the college introduced a number of new Web-based courses, no recognition was given to the faculty who had developed them.
 - d. A new policy requires faculty members to fill out daily reports accounting for all content they cover in their classes and explaining how they spend their time between classes.
12. Lisa, a waitress, feels like screaming. One of her customers ordered steak and shrimp, but when she brought it to him, he said he had ordered steak and lobster. If she tells him that he is wrong, she could lose a big tip. If she takes the food back to the cook, he might get angry and make mistakes with her

- orders all night long, which would also ruin her tips. This is an example of which kind of motivational conflict?
- Approach-approach
 - Approach-avoidance
 - Avoidance-avoidance
 - Multiple approach-avoidance
13. Which of the following is most important in determining one's level of subjective well-being?
- physical attractiveness
 - wealth
 - popularity
 - close social ties
14. When Harley received a letter from her fiancé that contained bad news, she experienced the fight-or-flight syndrome. This means Harley's
- parasympathetic nervous system was activated.
 - sympathetic nervous system was activated.
 - digestion and salivation were stimulated.
 - respiration and heart rate slowed.
15. Janet and Joan are experiencing identical patterns of physiological arousal: increased heart rate, sweaty palms, pupil dilation, and increased breathing rate. Janet feels happy, and Joan is very scared. Which of the following can explain the differences in their emotions?
- James's theory
 - Schachter's cognitive modification
 - Darwin's theory
 - Cannon's theory
16. Which theory requires the existence of unique physiological states for every emotion?
- James's
 - Cannon's
 - Schachter's cognitive modification
 - Darwin's
17. Lori and Carol are discussing the places in town where they have met the best-looking men. Based on your knowledge of transferred excitation, which place do you think would be at the top of their list?
- A men's clothing store
 - A laundromat
 - A local dance bar
 - A restaurant
18. Which of the following is the best example of facial feedback?
- Jill notices that Lani grimaces as Jill steps into her apartment without wiping her feet, so Jill stops to wipe them.
 - Someone comments that you are looking especially wonderful.
 - You notice that you are smiling as you study and conclude you must be in a good mood.
 - You look for evidence that your roommate is lying by scanning your roommate's face carefully.
19. People from many different cultures can recognize a smile as an indication of positive emotion. This suggests that at least some expressions of emotion are
- innate.
 - culturally determined.
 - learned.
 - lateralized.
20. A team of alien psychologists has landed in your backyard. They want to learn how to communicate emotions to humans. You would probably spend most of your time teaching them about
- body postures.
 - facial movements.
 - hand gestures.

d. voice inflections.

Total Correct (See answer key) _____

ANSWERS TO MULTIPLE-CHOICE QUESTIONS

Circle the question numbers you answered correctly.

Sample Quiz 1

1. *c* is the answer. Intervening variables help us understand why a given stimulus caused a given response. For example, hunger helps explain why someone ordered a pizza after hearing a pizza advertisement. The ad is the stimulus, and ordering the pizza is the response. The motive of hunger also explains why the person did not display some other response, such as ignoring the ad. (see Concepts and Theories of Motivation)
a, b, d. Motivation, motives, and needs are neither stimuli nor responses but can affect the responses made to stimuli.
2. *d* is the answer. Drives cause us to do things that will reduce needs such as hunger and thirst. Exploring a new environment doesn't reduce any known drive. (see Drive Reduction Theory)
a, b, c. Eating when hungry, drinking when thirsty, and making oneself warm are all behaviors that reduce drives.
3. *b* is the answer. An incentive theorist would say that Stewart was behaving in a way that he thought would bring him closer to a goal or an incentive. (see Incentive Theory)
a. An instinct theorist would say that Stewart has an aggressive instinct.
c. An arousal theorist would say that Stewart has a very high level of optimal arousal.
d. A drive theorist would say that Stewart wants the job so that he will have enough money to buy food.
4. *d* is the answer. Although it is generally found that women prefer men who are mature and wealthy while men prefer women who are young and healthy, this is not true of the Zulu. Among the Zulu, who have different gender roles, men value maturity and ambition in a mate more than women do. (see Instinct Theory and Its Descendants)
a. No research has shown that men in the United States are more ambitious than men in Canada. Even if this were true, this evidence would not be as strong as that from the Zulu.
b, c. These behaviors both fit with the evolutionary view that men look for women who are able to bear children and women try to look like they can do so.
5. *b* is the answer. Arousal theory states that people try to maintain an optimal level of arousal. According to arousal theory, Dwayne will seek relaxation when overaroused. (see Arousal Theory)
a. This would fit with incentive theory.
c, d. These sound similar to Maslow's views; however, he did not directly address arousal in his hierarchy of needs.
6. *a* is the answer. Cholecystokinin is a chemical that is involved in the cessation of eating. (see Biological Signals for Hunger and Satiety)

- b, c, d.* Cholecystokinin is not involved in the regulation of thirst, sex, or arousal.
7. *b* is the answer. People with bulimia can maintain a normal weight, but due to frequent vomiting, they experience dehydration, nutritional imbalances, and intestinal damage. (see Eating Disorders)
- a.* Those with anorexia have nutritional imbalances but do not maintain a normal weight. They starve themselves, causing a severe drop in weight.
- c.* Obese people are much heavier than they should be. They are at a higher risk for diabetes, heart attack, and high blood pressure.
- d.* *b* is the answer.
8. *c* is the answer. This 1994 survey found that people in the United States have sex less often and with fewer people than previously thought. Data also suggested that people in committed, monogamous relationships have the most frequent sex and the most satisfying sex. (see Focus on Research Methods: A Survey of Human Sexual Behavior)
- a, b.* People in committed, monogamous relationships reported the most frequent and most satisfying sex.
- d.* For most, sex occurs about once a week in monogamous relationships; about a third reported having sex only a few times or not at all in the past year.
9. *a* is the answer. Children whose parents encourage them to try new things and reward them for their successes develop a high need for achievement. (see Need for Achievement)
- b.* Children with parents who interfered in their work would not develop a high need for achievement.
- c.* Children with parents who let them give up would not develop a high need for achievement.
- d.* A lack of praise would *not* encourage development of a high need for achievement.
10. *a* is the answer. Physiological needs include food, water, oxygen, activity, and sleep. These are lowest on the hierarchy and, according to Maslow, are satisfied first. (see Maslow's Hierarchy)
- b.* Looking for inhabitants might satisfy belongingness needs but would probably be done after food and water had been found.
- c.* Establishing a form of self-government might satisfy belonging or esteem needs but would probably be done after food and water had been found.
- d.* Shelter is a safety need and would be satisfied after physiological needs.
11. *d* is the answer. According to the opponent-process theory, an opposing reaction can eventually motivate a behavior. The parachutists' initial reaction was extreme fear, and the opposing reactions were relief and excitement. After repeated jumps, the initial reaction decreased and the opponent reaction of euphoria took over the motivation. (see Opponent Processes, Motivation, and Emotion)
- a.* Arousal theory focuses on physiological arousal. Although the pilots were aroused by fear, they were overly aroused to the extent that they were urinating on themselves. Such an arousal is not strongly motivating. With repeated jumps, this arousal lessened.
- b.* Drive reduction theory says we seek to satisfy a need created when we experience an imbalance in homeostasis. Diving out of an airplane is not a biological need, nor is it described as being associated with a primary drive.
- c.* Incentive theory doesn't explain why parachutists would jump again after an initial harrowing experience. They would have no incentive to continue something that had caused fear and humiliation.
12. *b* is the answer. The situation of going to the concert has positive and negative features. (see Linkages: Conflicting Motives and Stress)
- a.* Approach-approach conflicts occur when a person tries to decide between two things, both of which have only positive features. The concert had negative as well as positive features.
- c.* Avoidance-avoidance conflicts are those in which a person must choose between two negative alternatives.
- d.* A multiple approach-avoidance conflict involves two situations, each of which has positive and negative features.

13. *b* is the answer. The Hanley brothers' experience of emotion fits best with Cannon's theory, which suggests that emotions take place in the brain but messages are simultaneously sent to the body. (see Cannon's Central Theory)
- a.* Schachter's modification of James's theory would suggest that physiological reactions can be labeled with different emotions, depending on the interpretation of the situation. In this scenario, immediate pleasurable emotion was experienced without interpretation.
 - c.* The thrust of James's theory is that there is no initial mental experience of emotion; rather, emotion is the result of the experience of bodily responses. In this scenario, the brain is primary in the experience of emotion.
 - d.* Arousal theory refers to motivation, not emotion.
14. *b* is the answer. Innocent people usually react more strongly to control questions such as, "Have you ever tried to hurt someone?" Therefore, Kurt should jam the tack in his toe after control questions, in order to produce physiological arousal. (see James's Peripheral Theory)
- a.* Questions about an alibi would not be good questions to seem upset about. Like questions that specifically refer to a crime, innocent people shouldn't react very strongly when asked about their whereabouts.
 - c.* Relevant questions are those that specifically refer to the crime. Guilty people react more strongly to relevant questions than to control questions.
 - d.* Reactions to relevant and control questions are compared in order to determine guilt or innocence. Questions about age, education, and income are neither control nor relevant questions.
15. *c* is the answer. People remain physiologically aroused longer than they think they do. The woman at the gym will feel calm by the time she is toweling off, even though she will still be somewhat aroused. If Matt approaches her at this point, she will probably attribute any leftover arousal to him instead of to the exercise. (see Cognitive Theories)
- a.* The woman at the gym will experience very little physiological arousal while she is warming up. If she does experience any arousal, she will attribute it to exercising, not to Matt.
 - b.* Weightlifting and aerobics will cause physiological arousal. However, the woman will probably attribute her arousal to these activities instead of to Matt.
 - d.* By the time the woman has showered and gone to the parking lot, she will no longer be aroused.
16. *b* is the answer. According to the James theory, there are unique changes in physiological arousal associated with each emotion. Frightened people do have cold feet because of decreased blood flow; therefore, fear may have a unique physiological response. (see James's Peripheral Theory)
- a.* According to the Cannon theory of emotion, physiological reactions do not play a role in the labeling of emotion because they occur at the same time as the emotion.
 - c.* Incentive theory is a theory of motivation.
 - d.* Schachter argued that a physiological reaction can be labeled with different emotions depending on a cognitive appraisal of the situation. Therefore, a unique physiological reaction is not necessary for each emotion.
17. *b* is the answer. An emotion culture is a set of rules that govern what emotions are appropriate in what circumstances and what emotional expressions are allowed. (see Social and Cultural Influences of Emotional Expression)
- a.* Extrinsic motivation is part of incentive theory. It is motivation due to expectation of external rewards.
 - c.* There is no such thing as a social referencing system. Social referencing refers to relying on cues from others when unsure of what is appropriate in ambiguous or strange situations.
 - d.* The pyramidal motor system is a brain system that controls voluntary facial movements. It is not related to this question.
18. *c* is the answer. According to the Schachter's cognitive modification of James's theory, if we attribute arousal to a nonemotional cause (for example, caffeine), then the experience of emotion should be

reduced. Gloria was not experiencing any emotion. She simply thought she had too much coffee that morning. (see Cognitive Theories)

- a. Darwin did not propose a theory of how we experience emotion.
 - b. According to the James theory, Gloria should have interpreted her physiological arousal as resulting from an emotion.
 - d. According to the Cannon theory, Gloria should have cognitively experienced an emotion when she felt the physiological arousal. This cannot be the answer since Gloria felt the arousal but no emotion.
19. *c* is the answer. James's theory suggests that we feel a physiological change and then perceive it as a specific emotion without considering the situation. (see James's Peripheral Theory)
- a. Arousal is a theory of motivation.
 - b. Cannon's theory states that the physiological reaction and emotion label will occur at the same time.
 - d. Schachter's cognitive modification of James's theory proposes that we make an attribution about the situation before experiencing the emotion.
20. *b* is the answer. Looking at another person to judge their emotional state as a guide for ours is social referencing. (see Social and Cultural Influences on Emotional Expression)
- a. The facial feedback hypothesis says that our own facial muscles give us information about our emotional state.
 - c. Attributions are the labels we assign to physiological arousal, according to the Schachter modification of James's theory of emotion.
 - d. Transferred excitation occurs when physiological arousal is unknowingly carried over into an unrelated situation.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 1 that you answered correctly.

Sample Quiz 2

1. *b* is the answer. Motivation is an intervening variable that explains the relationship between a stimulus and a response. Upon seeing a candy machine, a person makes one response if hungry and another if not hungry. Hunger is the intervening variable that explains the relationship between seeing the candy and buying it. (see Concepts and Theories of Motivation)
 - a. Salivation following the sound of a bell could be caused by classical conditioning. The rat was not necessarily motivated to salivate; it was just a reflex.
 - c, d. It isn't clear what the stimuli and responses are in either of these choices. A compliment or an attempt at cheerfulness may be motivated behavior, but it is unclear what the intervening variables would be.
2. *d* is the answer. Homeostasis is the process of maintaining an equilibrium in our physiological systems. Drives prompt us to behave in ways that maintain this balance or equilibrium. (see Drive Reduction Theory)
 - a. Instinct theorists said that our behavior occurs in response to specific stimuli rather than as a means of maintaining a balance in our systems.
 - b. Arousal theorists believe we behave in a certain way to maintain an optimal level of arousal, not to maintain a balance in our systems.
 - c. Incentive theorists believe we behave in ways that allow us to reach our goals of obtaining positive incentives and avoiding negative incentives.
3. *c* is the answer. Instincts are unlearned, automatic, innate responses to specific stimuli. (see Instinct Theory and Its Descendants)
 - a. According to arousal theory, we behave in ways that maintain our optimal level of arousal. Some of the activities that increase or decrease the level of arousal are probably learned.
 - b. According to drive theory, we learn secondary drives.

- d.* According to incentive theory, we behave in ways that allow us to reach certain goals. Some of the behaviors that allow us to reach certain goals are learned—for example, learning how to study in order to get good grades.
4. *c* is the answer. Vic is the wealthier, more mature male among the choices. (see Instinct Theory and Its Descendants)
- a.* The evolutionary approach emphasizes procreation. It hypothesizes that women seek a man with the ability to support children; therefore, a homosexual relationship would not be the best fit with this approach.
- b, d.* Tom and Wally do not have Vic's wealth and maturity; therefore, Tom and Wally are not as good a fit with the evolutionary approach to attraction and mating.
5. *b* is the answer. People with anorexia starve themselves and lose weight, in some cases to the point of death. (see Eating Disorders)
- a.* Obesity is characterized by eating more calories than necessary for body maintenance.
- c.* Bulimia nervosa is characterized by overeating and then inducing vomiting.
- d.* *b* is the answer.
6. *b* is the answer. Jack probably knew that most people consume 60 to 75 percent more food when they eat with others. Also, by definition a buffet would offer a variety of foods; Jack might also have known that he would probably eat more food if given more choices. (see Flavor, Cultural Learning, and Food Selection)
- a.* There is nothing in the question to suggest that Jack had lost his appetite. If anything, he would be hungry because he is on a restricted diet.
- c.* Jack would be able to select a balanced meal from the selection offered by the buffet.
- d.* Although culture influences our food preferences and eating habits, there is nothing in this question to suggest that Jack's cultural background would prevent him from dining with his roommates.
7. *c* is the answer. Feeling too hot is an unlearned need that will cause psychological arousal or a drive to motivate behavior to find some way of cooling off. (see Drive Reduction Theory)
- a.* Primary and secondary drives are addressed by the drive reduction theory. It does not describe cognitive drives.
- b.* The drive reduction theory doesn't include emotional drives; this is a made-up term.
- d.* Secondary drives are learned needs. If the question had said that Liz needed an extra job so that she could always have enough money to satisfy any primary drives, this would have been the correct alternative.
8. *c* is the answer. Men have more androgen than female hormones like progesterin and estrogen. (see The Biology of Sex)
- a.* Men do have female hormones like estrogen.
- b.* Men do not have more female than male hormones.
- d.* Men do have androgen; it is a male hormone.
9. *c* is the answer. It is important that Julie take the job that will yield the most satisfaction, which she will find in jobs that provide opportunities for advancement and individual responsibility. She should also take the job with the fewest dissatisfying characteristics, such as low pay and a mediocre boss. (see Need for Achievement)
- a.* Company 1 has very few dissatisfying characteristics but no satisfying characteristics either.
- b.* Company 2 offers a large amount of responsibility but several dissatisfying characteristics as well, such as low pay and a mediocre boss.
- d.* Company 4 has very few dissatisfying characteristics but no satisfying characteristics. The job carries no responsibility and does not provide any chances for advancement.
10. *c* is the answer. Maslow's hierarchy of five types of needs begins with biological needs and progresses through safety needs, interpersonal needs, respect and self-esteem needs, up to self-actualization.

According to Maslow, we will not be motivated to satisfy higher needs until the lower ones are met. Since Marta needs respect, her biological, safety, and intimacy needs must all have been satisfied. (see Maslow's Hierarchy)

a, b. Marta is motivated to gain respect, so her biological needs must have been satisfied, sufficiently so that being poor is not an issue.

d. If Marta had not had her lower needs satisfied, she would not be seeking respect, according to Maslow.

11. *b* is the answer. Research suggests that extrinsic rewards like pay raises are not the key to job satisfaction. Morale would not necessarily suffer because of the wage freeze. When employees suspect that they are seen as lazy, are given little credit for their accomplishments, and feel heavily supervised with little control over their time, morale and motivation will suffer. (see Achievement and Success in the Workplace)

a, c, d. All of these will have a strong negative effect, leading to employee dissatisfaction and decreased motivation to do good work.
12. *c* is the answer. Lisa is in a situation in which she faces two negative outcomes: The cook will probably be angry, and the customer will probably be irritated. This is characteristic of an avoidance-avoidance situation. (see Linkages: Conflicting Motives and Stress)

a. An approach-approach situation is a choice between two equally positive alternatives.

b. An approach-avoidance situation is a choice that has both a positive and a negative aspect.

d. A multiple approach-avoidance situation is a choice between two situations, each of which has a positive and a negative aspect.
13. *d* is the answer. Close social ties are one of the most important factors in determining subjective well-being. (see Achievement and Subjective Well-Being)

a, b, c. These environmental factors are not strongly associated with subjective well-being.
14. *b* is the answer. The fight-or-flight syndrome is a pattern of increased blood pressure and heart rate, rapid breathing, and dry mouth, among other symptoms, that comes when the sympathetic nervous system has been activated. (see The Biology of Emotion)

a. The parasympathetic nervous system is responsible for calming the body. Its activity decreases during the fight-or-flight response.

c, d. When the sympathetic nervous system is activated, digestion and salivation decrease while respiration and heart rate increase.
15. *b* is the answer. According to Schachter's cognitive modification of James's theory, our cognitive appraisals of situations can cause us to label identical physiological responses in several different ways. (see Cognitive Theories)

a. According to the James theory, every emotion is associated with a unique physiological response.

c. Darwin did not address the mechanism that labels emotions. He said that emotional expressions are inherited.

d. Cannon thought the perception of and the experience of the emotion were simultaneous. He did not discuss cognitive appraisal.
16. *a* is the answer. The James theory of emotion states that we experience emotion based on our physiological responses. If this is true, every emotion should be associated with a unique pattern of physiological arousal. (see James's Peripheral Theory)

b. According to the Cannon theory, the thalamus is the core of emotion. Peripheral responses do not determine which emotion we are feeling.

c. According to Schachter, the same pattern of physiological arousal can be attributed to different emotions based on our cognitive appraisal of the environment. Therefore, it is not necessary to have unique patterns of physiological arousal for every emotion.

d. Darwin discussed the functions that emotion serves in survival.

17. *c* is the answer. Research has shown that, compared with people at rest, exercise-aroused people experience stronger feelings of attraction when they meet people of the opposite sex. When Lori and Carol get off the dance floor, they will transfer the excitation caused by dancing to the attractive men they see in the bar. (see Cognitive Theories)
- a, b, d.* A clothing store, laundromat, and restaurant do not offer any activity that causes an increase in physiological arousal.
18. *c* is the answer. The facial feedback hypothesis is a variation on James's theory. It suggests that facial movements are information we interpret as part of our physiological response. According to James, we have a different set of facial expressions and bodily responses for each emotion. Some evidence shows that smiling will make a person feel happier. (see James's Peripheral Theory)
- a.* This is an example in which Jill has used social referencing to adjust her behavior.
- b.* A compliment may be feedback that you look nice, but it is not part of the facial feedback hypothesis.
- d.* The facial feedback hypothesis proposes that feedback from our own faces informs us of our emotions. It does not deal with looking at other people's faces for evidence of emotion or lies.
19. *a* is the answer. Something innate should not be affected to any great degree by cultural influence. People from many different cultures all relate smiles to positive emotions. (see Innate Expressions of Emotion)
- b, c.* Events that are culturally determined or only learned are usually different in every culture. If expressions of happiness were culturally determined or learned, every culture would interpret a smile in a different way. However, this is not the case. All cultures relate smiling to positive emotion.
- d.* There is no causal relationship between universal recognition of emotion and the particular structure of the nervous system responsible for emotional recognition.
20. *b* is the answer. In humans, the face communicates emotions better than any other part of the body. (see Social and Cultural Influences on Emotional Expression)
- a, c, d.* Body posture, hand movements, and voice inflection communicate emotions, but facial expressions are more important.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 2 that you answered correctly.

For each question you answered correctly, circle its number. (Quiz 1 numbers are not shaded; Quiz 2 numbers are shaded.) Are there patterns in the types of questions or the topics you got wrong that could direct your further study? Did you improve from Quiz 1 to Quiz 2?

CHAPTER 12

Human Development

MULTIPLE-CHOICE QUESTIONS

Sample Quiz 1

1. Most contemporary developmental psychologists believe that development is guided by
 - a. maturational processes.
 - b. the influence of external conditions.
 - c. the interaction of nature and nurture.
 - d. biological processes.
2. Colleen is five years old, has mental retardation, and has a malformed face. What probably occurred during Colleen's prenatal development?
 - a. Colleen was exposed to a teratogen.
 - b. Her mother experienced severe stress.
 - c. Colleen's mother did not provide a stimulating environment for her.
 - d. Colleen's zygote period was skipped.
3. Penny is going to decorate her newborn's room and wants the baby to enjoy looking all around it. Which of the following will meet her decorating needs?
 - a. Wallpaper covered with very small blue flowers
 - b. A mobile with very small butterflies for the far end of the room
 - c. Curtains with large smiling clown faces for the window right next to the baby's bed
 - d. A wall hanging of gray and white checked fabric
4. The development of the cardiovascular and nervous systems and the organs begins during which stage of prenatal development?
 - a. Germinal
 - b. Embryonic
 - c. Fertile
 - d. Fetal
5. Why do infants have reflexes?
 - a. They help babies survive.
 - b. They are unnecessary evolutionary leftovers.
 - c. They speed development.
 - d. Psychologists are in serious disagreement on this issue.
6. Object permanence is acquired during Piaget's _____ period of cognitive development.
 - a. formal operations
 - b. concrete operations
 - c. preoperational
 - d. sensorimotor

7. Gary's parents are constantly amazed at how their son has changed over the past year. Suddenly, he loves to study science, is a feminist, and wants to participate in an anti-nuclear-power demonstration. Gary has moved into the _____ stage of cognitive development.
 - a. sensorimotor
 - b. preoperational
 - c. concrete operations
 - d. formal operations
8. Jeffrey learned to pick up bits of cereal and push his fingers and the cereal into his mouth. Jeffrey discovered, however, that this method did not work for yogurt and eventually learned that yogurt is eaten with a spoon. Jeffrey's modified behavior shows
 - a. accommodation.
 - b. assimilation.
 - c. conservation.
 - d. object permanence.
9. Which of the following statements does *not* reflect current thinking on why we cannot remember events from before the age of three?
 - a. Early events tend to be fused into general event representations.
 - b. We don't begin to form mental representations of objects and actions before age three.
 - c. Before age three we don't have the language skills to talk about and solidify memories.
 - d. Schemas we use in early childhood to represent memories change in later years.
10. Claude pretends to be a baker while playing in the sand. He forms five sand cookie balls. Then he forms a sixth but flattens it into a pancake. "Wow!" he exclaims, "This is a much bigger cookie than the other ones!" According to Piaget, Claude is in the _____ stage of cognitive development.
 - a. concrete operations
 - b. formal operations
 - c. preoperational
 - d. sensorimotor
11. In assimilation,
 - a. information is added to existing schemas.
 - b. old schemas are modified.
 - c. schemas are eliminated.
 - d. none of the above
12. An authoritative parent is
 - a. firm, punitive, and unsympathetic.
 - b. very lax about discipline and gives the child complete freedom.
 - c. firm but reasonable and explains why a child's behavior is incorrect.
 - d. one who demands obedience to authority.
13. It is interesting to watch nine-month-old P.J. react to a new object. He holds onto his mother very tightly for several long moments and then, using the furniture to steady himself, walks toward the object and warily checks it out. P.J. has a temperament that is typical of
 - a. easy babies.
 - b. difficult babies.
 - c. slow-to-warm-up babies.
 - d. exploratory babies.
14. Woody's parents gave him a strict curfew, never allowed him to visit with friends until homework was finished, and did not discuss their reasons for the rules. When Woody wrote his first play, they punished him for wasting his time when he should have been studying. Woody's parents have which parenting style, according to Baumrind?
 - a. Authoritarian
 - b. Authoritative
 - c. Insecure
 - d. Permissive

15. Gloria is forty years old and is beginning to feel the need to produce something that will outlast her, whether it be a child or an achievement at work. According to Erikson, Gloria is facing a(n) _____ crisis.
- intimacy
 - integrity
 - generativity
 - autonomy
16. The Woodleys are concerned because both need to work and they must put their infant into day care. What would you tell them?
- Their baby will be at risk for emotional problems.
 - Their baby will be at risk for behavioral problems.
 - If they are sensitive and responsive and it is a quality day-care situation, the child should not be at risk for any problems.
 - They should not worry; infants are amazingly adaptable and will not develop problems, no matter what the situation.
17. Tenita is an infant who is learning that she will be fed, clothed, and kept warm and dry. Tenita is most likely in Erikson's _____ stage of psychosocial development.
- intimacy versus isolation
 - integrity versus despair
 - generativity versus stagnation
 - trust versus mistrust
18. During Kohlberg's conventional level of moral reasoning, children
- consider what they will gain by the moral decision.
 - choose an action that will bring approval.
 - make decisions from a human rights perspective.
 - make decisions based on their personal standards.
19. Cognitive abilities first begin to decline during
- middle age (forty to sixty-five).
 - late adulthood (sixty-five to seventy-six).
 - old age (seventy-five and older).
 - late early adulthood (about age thirty-five).
20. Generally speaking, who among the following is most likely in the midst of a midlife crisis?
- Abby, who is filing for divorce
 - Ben, who is considering whether to continue his education and earn a master's degree
 - Cathy, who is torn between maintaining a career she spent years developing or getting pregnant before it is too late to have children
 - Danny, who is considering marriage

Total Correct (See answer key) _____

Sample Quiz 2

Use this quiz to reassess your learning after taking Quiz 1 and reviewing the chapter.

- In the context of the nature-nurture debate, nurture could be defined as
 - a child's education.
 - the sensitivity of the parent's care.
 - a healthy diet.
 - All of the above
- Lillian is not an alcoholic; she never drinks to excess. However she does have wine with dinner every evening. Lillian, who is two weeks pregnant, has asked you whether this can injure her baby. What response could you correctly give her?
 - Since Lillian is not an alcoholic, wine will probably not injure the baby.
 - Since Lillian doesn't overindulge, wine will probably not injure the baby.
 - Scientists still do not know the effects of wine drinking on unborn children.

- d. Even one glass of wine a day can cause damage to the unborn child.
3. Suppose a research team finds that an experimental drug causes heart abnormalities in rats, but only if it is given between day seven and day ten of gestation. These researchers have identified a(n) _____ period.
- germinal
 - precocial
 - critical
 - artificial
4. What types of sounds do infants prefer?
- Soothing descending tones
 - Low pitches
 - Monotones
 - High pitches
5. A teratogen is a
- genetic abnormality.
 - period during which the fetus is susceptible to birth defects.
 - substance that can cause birth defects.
 - person whose characteristics are caused by fetal alcohol syndrome.
6. Joey is six months old and loves to play "tug-of-war." When his dad leans over the crib with a toy in his hand, Joey grasps it and pulls on it. Joey's mom just got him a new toy—a little string of colored animals—to hang across his crib. She does not understand why Joey always reaches up and pulls down the string of colored animals. Joey is elaborating his schema of grasping and pulling through
- accommodation.
 - integration.
 - assimilation.
 - anticipation.
7. Stasha enjoys putting all kinds of objects, including bugs and dirt, in her mouth. She loses interest in playing with her toy train, however, when her babysitter hides it. Stasha is most likely in Piaget's _____ stage of cognitive development.
- concrete operations
 - formal operations
 - preoperational
 - sensorimotor
8. Susie is crying because her teddy bear, Boyd, has fallen off the kitchen table and landed on its face. She insists that her mother should put a bandage on Boyd's nose. Susie is in Piaget's _____ stage of cognitive development.
- sensorimotor
 - preoperational
 - formal operations
 - concrete operations
9. Understanding that a substance's quantity doesn't change, even when its form does, occurs during which of Piaget's developmental stages?
- Sensorimotor
 - Preoperational
 - Concrete operational
 - Formal operational
10. The development of the ability to use symbols occurs during the period.
- sensorimotor
 - preoperational
 - concrete operational
 - formal operational

11. Temperament is first recognizable at what stage of development?
 - a. Birth
 - b. Preoperational period
 - c. Adolescence
 - d. Middle childhood
12. Two mothers are assessing their children's abilities. One turns to the other and says, "Of course Juan is doing better at math. Now that he is older, his concentration is better and he can hold more chunks of information in his memory at the same time." _____ would agree with Juan's mom.
 - a. Piaget
 - b. Erikson
 - c. An information-processing theorist
 - d. Kohlberg
13. Sherri babysits for Peter every afternoon and has noticed that he cries and fusses when his mother leaves. When his mother returns, Peter squirms and refuses to be held by her. Peter most likely has
 - a. a secure attachment.
 - b. an anxious insecure attachment.
 - c. a secure avoidant attachment.
 - d. a secure ambivalent attachment.
14. Betty is very careful to keep her new baby boy clothed and well-fed and to change his diaper when needed. She does not hold or touch him much because she thinks that this will spoil him and make him too dependent. Based on Harlow's studies, what should you tell Betty?
 - a. Since humans are an intelligent species, their young can thrive well without being held much.
 - b. Babies need to be touched and held to develop normally.
 - c. Only a parent bonds with an infant, an infant does not bond with a parent.
 - d. Humans do not usually form true attachments until they are eighteen months old.
15. Sam and Akbar want to attend a rock concert in New York City on July 4th. Sam's parents have told him that, although they understand his frustration, it is too dangerous for a fourteen-year-old to travel to the city by himself on a big holiday. Meanwhile, Akbar's parents have decided that he may go to the concert. Sam's parents are _____ and Akbar's parents are _____.
 - a. permissive, authoritative
 - b. authoritarian, permissive
 - c. authoritative, authoritarian
 - d. authoritative, permissive
16. Which of these statements regarding children's social skills is *incorrect*?
 - a. Parents can aid the development of cooperative interaction by initiating pretend play.
 - b. Children who do not learn to detect others' emotional signals are often rejected by their peers.
 - c. Children who cannot control their emotions are often unsympathetic and unhelpful.
 - d. Empathy does not need to be learned; children develop it naturally.
17. Misha recently graduated from high school and is unsure about going to college. She hasn't picked out a career, but wonders if taking courses would help her to decide who she is and what she wants to do. Erikson most likely would say Misha is in the midst of an
 - a. initiative conflict.
 - b. autonomy conflict.
 - c. integrity crisis.
 - d. identity crisis.
18. Jeanine and Helen are in a drugstore spending several weeks' worth of allowance on candy. Helen decides she wants to steal the candy, but Jeanine argues that they might get caught and put in jail. According to Kohlberg, Jeanine is at which level of moral reasoning?
 - a. Preconventional
 - b. Conventional
 - c. Concrete
 - d. Postconventional

19. Omar, a native of Nigeria whose family recently emigrated to the United States, has enrolled in ninth-grade classes. He is developing a sense of himself but is having concerns over his ethnic identity. What difficulty may Omar be experiencing?
- He is unsure of what he wants to do in the future.
 - Although he is African, he does not identify with African-American culture.
 - He is unsure of where he wants to live in the future.
 - He has been investigating various moral philosophies lately.
20. Which of the following is a key to longevity?
- Having an abundance of money
 - Remaining physically and mentally active
 - Preparing for death
 - Retiring as early as possible
- Total Correct (See answer key) _____

ANSWERS TO MULTIPLE-CHOICE QUESTIONS

Circle the question numbers you answered correctly.

Sample Quiz 1

- c is the answer. The nature of inherited genes can explain how people are alike in certain respects, and the nurture of widely different family and cultural environments produce differences among individuals. (see Exploring Human Development)

 - Arnold Gesell in the early 1900s suggested that human development is determined by nature and is relatively unaffected by the environment.
 - Early in this century John Watson believed that development is guided solely by learning.
 - Biological processes would be synonymous with nature, or maturation.
- a is the answer. Teratogens are harmful external substances that invade the womb and result in birth defects. (see Prenatal Development)

 - Stress levels of the mother can affect the child, but they do so in subtler ways that are reversible. There is no evidence that stress levels could cause these overt problems.
 - If a pregnant woman maintains a healthy lifestyle and gets adequate prenatal care, the fetus will develop into a healthy baby. No extra stimulation of the unborn child is needed.
 - If the zygote period was skipped, conception never occurred.
- c is the answer. Infants can see large objects featuring lots of contrast, contour, complexity, and movement. They enjoy looking at faces. The clown faces are large and smiling and may move with the breeze. (see The Newborn)

 - This wallpaper design may appeal to Penny, but her infant will not have the visual capability to see the small pattern.
 - A mobile is a good idea because the parts move, but the infant will be unable to see it in the far corner.
 - A wall hanging of brightly colored checks may provide enough contrast for the infant to see it. However, grey and white are not as contrasting as, say, blue and red.
- b is the answer. Cardiovascular and nervous systems develop during the embryonic stage. A critical period exists: If certain systems and organs do not develop properly at this time, they never will. (see Prenatal Development)

 - The germinal stage begins with fertilization and lasts for two weeks. The zygote divides rapidly, travels down the Fallopian tubes, and attaches to the uterine wall.
 - d. There is no such thing as the fertile stage in prenatal development. You may be thinking of the fetal stage. During this stage, systems integrate and the organs grow and begin to function more efficiently.

5. *a* is the answer. Because human babies are so helpless at birth, reflex movements help babies survive. Imagine trying to teach a day-old infant the mouth movements involved in sucking. By the time the baby learned, he or she would have starved. (see *The Newborn*)
 - b*. Reflexes are necessary; they help babies survive.
 - c*. Reflexes do not speed development, but they do help babies survive while their muscles are developing.
 - d*. Psychologists agree on the role of reflexes.
6. *d* is the answer. Object permanence is the ability to know that an object exists even when it is out of sight. Children acquire this ability during the sensorimotor period, the first stage of cognitive development. (see *The Development of Knowledge: Piaget's Theory*)
 - a*. An adolescent acquires the ability to think hypothetically and to imagine logical consequences of events in the formal operational period.
 - b*. A child learns to perform simple operations—subtraction, addition, classification, seriation, and conservation—during the concrete operational period.
 - c*. A child acquires the ability to use symbols during the preoperational period.
7. *d* is the answer. Studying science involves thinking logically and being able to generate hypotheses. Being involved with feminist movements and nuclear demonstrations requires the ability to question social institutions and to think about the world as it might be or as it ought to be. (see *The Development of Knowledge: Piaget's Theory*)
 - a, b*. Children in the sensorimotor or preoperational periods do not have the ability to question social institutions. They may have some knowledge of feminism or nuclear power plants, but they cannot think about or accurately imagine the consequences of nuclear disasters or the treatment of women as inferior.
 - c*. During the concrete operations period, children can think logically about objects they directly experience.
8. *a* is the answer. In accommodation, new information changes a schema. (see *The Development of Knowledge: Piaget's Theory*)
 - b*. Assimilation is when new information is added to an unchanged schema.
 - c*. Conservation is the ability to realize that the size, quantity, or mass of an object is the same although it looks different.
 - d*. Children with object permanence know that an object exists even when it is hidden from view.
9. *b* is the answer. Psychologists now believe that infants are thinking, as well as sensing and moving. (see *Linkages: Development and Memory*)
 - a, c, d*. These are all possible explanations for infantile amnesia.
10. *c* is the answer. Claude cannot perform the mental operations needed to conserve amounts (understand that although shapes may change, the amounts remain the same). Therefore, Claude is in the preoperational stage. (see *The Development of Knowledge: Piaget's Theory*)
 - a*. Concrete operations require the ability to conserve.
 - b*. Formal operations require the ability to think about abstract concepts.
 - d*. Infants in the sensorimotor period explore the world through their senses. They do not have object permanence until the end of the sensorimotor period and cannot conserve amounts. Because Claude is pretending, however, we know that he has moved beyond the sensorimotor stage.
11. *a* is the answer. (see *The Development of Knowledge: Piaget's Theory*)
 - b*. In accommodation, old schemas are modified with new information.
 - c*. Schemas are enlarged in assimilation or are changed in accommodation, but they are not eliminated.
 - d*. *a* is the answer.
12. *c* is the answer. Authoritative parents are firm but reasonable and provide explanations when a child's behavior is incorrect. They encourage the child to take responsibility and to be independent. (see *Relationships with Parents and Peers*)

- a.* Authoritarian parents are firm, punitive, and unsympathetic.
 - b.* Permissive parents are very lax about discipline and give their children complete freedom.
 - d.* Authoritarian parents demand obedience to authority figures.
- 13. *c* is the answer. (see Individual Temperament)
 - a.* An easy baby has predictable cycles of eating and sleeping, reacts cheerfully to a new situation, and seldom fusses.
 - b.* A difficult baby is irritable and irregular.
 - d.* Although some infants are more exploratory than others, there is no category or classification termed "exploratory."
- 14. *a* is the answer. Authoritarian parents are strict and unyielding disciplinarians. (see Relationships with Parents and Peers)
 - b.* Authoritative parents discuss rules and are more affectionate.
 - c.* Baumrind did not use the term insecure to describe parents.
 - d.* Permissive parents are less informed about their children's activities. They set few rules and rarely use discipline.
- 15. *c* is the answer. Erikson said that in middle adulthood people become concerned with generating or producing something that will outlast them. (see Social Changes)
 - a.* Erikson said that concerns about intimacy are dealt with in early adulthood.
 - b.* Integrity vs. despair is the social conflict dealt with in late adulthood, according to Erikson.
 - d.* Autonomy or independence is the challenge of the toddler, according to Erikson.
- 16. *c* is the answer. Day care by itself does not lead to insecure attachment or emotional harm. Responsive and caring parents and quality day care should result in secure infant-adult attachments. (see Thinking Critically: Does Day Care Harm the Emotional Development of Infants?)
 - a, b.* Day care by itself does not lead to insecure attachments or emotional harm.
 - d.* If day care is of poor quality and caregivers are insensitive and unresponsive, infants will be less likely to develop secure attachments.
- 17. *d* is the answer. Infants learn whether the world is a predictable place during the trust versus mistrust crisis. If their needs are met, they will most likely resolve the crisis successfully. (see Relationships with Parents and Peers)
 - a.* Intimacy versus isolation occurs in early adulthood.
 - b.* Integrity versus despair occurs in late adulthood.
 - c.* Generativity versus stagnation occurs in middle adulthood.
- 18. *b* is the answer. Children at the conventional level make moral decisions based on other people's approval or on what everyone else says is right. (see Abstract Thought and Moral Reasoning)
 - a.* This is the preconventional level, which is basically characterized by selfishness.
 - c, d.* Both of these choices describe reasoning at the postconventional level of moral reasoning, when decisions are based on personal standards or respect for human rights.
- 19. *b* is the answer. Decline of abilities that require rapid and flexible manipulations of ideas and symbols, active thinking and reasoning, and sheer mental effort is first noted in some people after about age sixty-five. (see Cognitive Changes)
 - a, d.* In early and middle adulthood important cognitive abilities improve.
 - c.* Decline of these abilities tends to occur before age seventy-five.

20. *c* is the answer. Around age forty, men and women may reappraise their lives and relationships. A woman who initially chose career over family may begin to wonder if she could still have children. (see Social Changes)
- a*. Divorce may occur at any time in adult life. It is not specifically a challenge of middle adulthood.
- b, d*. Although not specifically restricted to early adulthood, questions about career, schooling, and marriage are usually faced during that period.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 1 that you answered correctly.

ANSWERS TO MULTIPLE-CHOICE QUESTIONS

Circle the question numbers you answered correctly.

Sample Quiz 2

1. *d* is the answer. Nurture is anything in the environment that influences an organism, including education, parents' care, physical exercise, and diet. Nature is any characteristic resulting from inherited genetic material, such as eye color or a physical predisposition toward a disease, body type, or temperament. (see Exploring Human Development)
- ~~— *a, b, c*. Each of these choices is correct, but no one of them is the *best* answer.~~
2. *d* is the answer. Pregnant women who drink as little as a glass or two of wine a day can harm their infants' intellectual functioning. (see Prenatal Development)
- a, b, c*. Only *d* is correct.
3. *c* is the answer. The critical period in prenatal development is the time when certain kinds of growth must occur if development is to proceed normally. If something happens during this time, abnormalities will result. The drug given to rats during that critical three-day period resulted in heart abnormalities. (see Prenatal Development)
- a*. The germinal stage is a general term for the first two weeks of prenatal development. It does not refer to times when growth may be interrupted, as described in this question.
- b, d*. These terms are not used in connection with periods of prenatal development in human beings.
4. *d* is the answer. (see The Newborn)
- a, b, c*. Infants prefer ascending tones, spoken by a woman or a child. They like speech that is friendly, high-pitched, exaggerated, and expressive.
5. *c* is the answer. Teratogens are external substances that can cause birth defects when taken into the womb during pregnancy. (see Prenatal Development)
- a*. Teratogens are external causes of problems; they are not genetic defects.
- b*. The critical period is during the embryonic stage. Teratogens are especially dangerous then.
- d*. A baby with fetal alcohol syndrome is not called a teratogen. Alcohol is the teratogen.
6. *c* is the answer. Joey is assimilating because he is using the *same* schema of reaching and grasping to investigate a new object. (see The Development of Knowledge: Piaget's Theory)
- a*. Accommodation occurs when a schema is modified or changed in response to acquiring new information. If the question stated that Joey learned to push the animals back and forth in the air instead of always reaching, grasping, and pulling them down, accommodation would have been the answer.
- b*. Integration is the process of putting two schemas together. If the question stated that Joey learned that reaching and grasping can become a sequence of movements, this would be the correct answer.
- d*. There is no anticipatory process in the elaboration of schemas.

7. *d* is the answer. Children in the sensorimotor period, according to Piaget, are still acquiring object permanence. They often put things in their mouths to see how they feel. (see The Development of Knowledge: Piaget's Theory)
 - a. Concrete operational children have acquired object permanence and do not explore the world by putting objects in their mouths.
 - b. Adolescents or adults in formal operations think abstractly.
 - c. Preoperational children have object permanence.
8. *b* is the answer. Susie is probably between the ages of four and six and thinks that her bear, an inanimate (nonliving) object, is alive and feels pain because he fell on his face. Mom typically puts a bandage on Susie's cuts and bruises, and Susie wants the same treatment for Boyd. This behavior is characteristic of the preoperational stage. (see The Development of Knowledge: Piaget's Theory)
 - a. Children in the sensorimotor stage do not recognize or label their own emotions, and therefore cannot assume that their toys have emotions.
 - c. Adolescents in the formal operational stage realize that inanimate (nonliving) objects do not feel pain.
 - d. Children in the concrete operational stage realize that inanimate (nonliving) objects do not feel pain.
9. *c* is the answer. (see Linkages: Development and Memory)
 - a. The sensorimotor period starts with birth and extends through two years of age.
 - b. Conservation—understanding that substances don't change in quantity even when their shape does—is an "operation." In the *preoperational* period, children cannot perform this "operation."
 - d. Adolescents in the formal operational period already understand concrete operations.
10. *b* is the answer. The ability to use symbols is a cognitive development that occurs during the preoperational stage. (see Abstract Thought and Moral Reasoning)
 - a. Object permanence is one of the principle cognitive developments that occur during the sensorimotor period.
 - c. A child in the period of concrete operations not only can use symbols as mental representations but can also manipulate those symbols in simple logical operations.
 - d. When an adolescent reaches the stage of formal operations, he or she is capable of abstract reasoning, far beyond the simple use of symbols.
11. *a* is the answer. (see Individual Temperament)
 - b, c, d. While temperament is recognizable during the preoperational period, adolescence, and middle childhood, it *first* appears at birth.
12. *c* is the answer. Developmental research based on information-processing theory focuses on the *quantitative* changes in children's mental capacities, rather than looking for qualitative advances or changes as Piaget did. *Better* concentration and retention of *more* chunks of information in memory at one time are all quantitative changes. Therefore, Johnny's mother is explaining her son's improvement as an information-processing theorist would. (NOTE: This approach focuses on quantitative changes. *Quantitative* pertains to number or amounts; so *bigger* or *more* ability accounts for a change, according to this view of cognitive development.) (see Information Processing During Childhood)
 - a. Piaget explained that cognitive development pertains to a *different* kind of mental ability, not just an improved ability for the same cognitive skill. The use of symbols (acquired during the preoperational period) is different from the ability to generate hypotheses (acquired during the formal operation period). (NOTE: *Quality* is defined as "a distinguishing element or characteristic." And each stage of Piaget's cognitive development theory is distinguished by a *unique* characteristic or type of thinking.)
 - b. Erikson studied the stages of emotional development.
 - d. Kohlberg was interested in moral decision making—only one type of cognitive activity. His work does not provide a general theory about the development of cognitive abilities.
13. *b* is the answer. (see The Infant Grows Attached)
 - a. A child who can tolerate brief separation from his or her mother, but who welcomes contact with the mother when she returns, has a secure attachment.
 - c. There is no such thing as a secure avoidant attachment.
 - d. There is no such thing as a secure ambivalent attachment.

14. *b* is the answer. Betty's baby could experience dramatic problems due to developmental brain dysfunction and damage brought on by the lack of touch and body movement in infancy. (see The Infant Grows Attached)
 - a*. The need for comfort and connection has nothing to do with intelligence.
 - c, d*. Infants form attachments, or bonds, to caregivers during the first year of life.
15. *d* is the answer. Authoritative parents would be sympathetic (sorry that Sam has to miss the concert) but their decision would stand firm. Akbar's parents give him complete freedom and are therefore permissive. Neither set of parents is authoritarian in the sense of firmly upholding rules with no explanation. (see Relationships with Parents and Peers)
16. *d* is the answer. Social skills, like cognitive skills, must be learned. (see Social Skills)
 - a, b, c*. All of these are true statements regarding children's social competencies and skills.
17. *d* is the answer. Misha doesn't have the feeling that she is a unique person; she is still confused about her self-image and her role in life. (see Identity and Development of the Self)
 - a, b*. Conflicts dealing with initiative and autonomy occur during early childhood according to Erikson.
 - c*. The issue of integrity is faced during late adulthood, according to Erikson.
18. *a* is the answer. The preconventional level of reasoning is very self-serving. Moral decisions are made either to avoid punishment or to benefit the individual. The only reason Jeanine gives for not stealing the candy is avoiding potential punishment. (see Abstract Thought and Moral Reasoning)
 - b*. At the conventional level of moral reasoning, Jeanine would be concerned with doing what attained the approval of others or with following the rules.
 - c*. There is no such level in Kohlberg's model. You may have been thinking of Piaget's concrete operational period.
 - d*. At the postconventional level of moral reasoning, Jeanine would be concerned with universal principles of human rights or with personal standards of justice.
19. *b* is the answer. As part of the development of his personal identity as a unique individual, Omar must come to terms with that part that reflects his race, religion, and culture. Because his Nigerian culture differs not only from that of the majority culture in the United States, but also from that of the U.S. African-American subculture, he may have difficulty figuring out what his ethnic identity is and feeling comfortable with it. (see Identity and Development of the Self)
 - a, c, d*. None of these is particularly concerned with the particular question of ethnic identity as addressed in the question.
20. *b* is the answer. Living as long as possible is associated with engaging in regular physical and mental exercise. (see Longevity)
 - a, c, d*. None of these has been connected with longevity.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 2 that you answered correctly.

For each question you answered correctly, circle its number. (Quiz 1 numbers are not shaded; Quiz 2 numbers are shaded.) Are there patterns in the types of questions or the topics you got wrong that could direct your further study? Did you improve from Quiz 1 to Quiz 2?

CHAPTER 13

Health, Stress, and Coping

MULTIPLE-CHOICE QUESTIONS

Sample Quiz 1

1. Which of the following is true of stress measurement?
 - a. Stressors always involve major life events.
 - b. Major stressors have a greater impact than several minor stressors.
 - c. Sometimes consistent daily hassles cause severe stress reactions.
 - d. Only a combination of major and minor stressors causes a severe stress reaction.
2. Which of the following would *not* be considered a stressor?
 - a. Taking a three-week vacation
 - b. Planning a wedding reception for five hundred guests
 - c. Being able to hear the neighbor's baby cry
 - d. All of the above are stressors.
3. The fight-or-flight syndrome is part of the _____ stage of the GAS.
 - a. resistance
 - b. alarm
 - c. exhaustion
 - d. adaptation
4. Mario has been working two jobs for the past year and is taking a full load of classes. Mario is tired, irritable, and depressed. His bosses and teachers are concerned because the quality of his work has gradually decreased. Which of the following is Mario most likely experiencing?
 - a. A behavioral stress response
 - b. Burnout
 - c. A disease of adaptation
 - d. Posttraumatic stress disorder
5. Overarousal can cause
 - a. increased performance on nonpracticed tasks.
 - b. clear and less muddled thinking.
 - c. a reliance on mental sets.
 - d. enhanced information processing.
6. Which of the following describes a person at the resistance stage of the general adaptation syndrome (GAS)?
 - a. Chung Wha feels fine but has a high level of corticosteroids.
 - b. Abel gets one head cold after another during an entire semester.
 - c. Elle's muscles are tense, her heart rate is increasing, and she is breathing hard.
 - d. Lee has an ulcer but is treating it with prescription medicines.
7. Which of the following has been said of Selye's general adaptation syndrome?
 - a. It underemphasizes the biological processes involved in stress response.
 - b. It adequately explains the contribution of psychological factors in reactions to stress.
 - c. It overemphasizes the contribution of psychological factors in the determination of stress responses.
 - d. It underemphasizes the psychological processes involved in stress responses.
8. Melissa and Randy both have mountains of work on their desks. Melissa rolls up her sleeves in eager anticipation. She knows the project in front of her will earn her a promotion. Randy cringes every time he walks into his office and surveys the mess. He can think only of how long it is going to take him to finish. Which of them will experience the most stress?
 - a. Melissa, because she is worried about getting promoted
 - b. Randy, because he interprets the work as a stressor
 - c. Melissa, because women are more prone to stress than men
 - d. Randy and Melissa, because they both experience an equally large amount of stress

9. Julie is feeling stress while completing a midterm exam. According to your text, which of the following would most likely reduce the amount of stress Julie is feeling?
 - a. The teacher said the test would be true-false questions, but it is essay format.
 - b. She thinks she is going to flunk the test.
 - c. She knew that the test would be hard.
 - d. She doesn't know anyone else in the class.
10. Wing knew he had to quit smoking because his breathing was painful and labored after climbing just a few stairs. Also, he had watched his favorite uncle suffer through lung cancer and die a horrible death. Wing knew that if he quit soon, many of the problems in his respiratory system would likely reverse themselves. Finally, he knew that the benefits of quitting would outweigh the discomfort. What did Wing still lack that would probably prevent him from trying to quit?
 - a. Sufficient physical suffering and problems
 - b. A belief that he could quit
 - c. Fear of consequences
 - d. Specific rewards for quitting
11. Fenster's car was hit from behind by a speeding drunk driver, causing his van to slam into the car in front, pushing it into the path of an oncoming cement truck. Two girls in that car were killed instantly. Although the accident wasn't his fault and there was nothing he could have done to avoid hitting the girls' car, Fenster began experiencing nightmares and severe feelings of guilt. Fenster was probably suffering from
 - a. burnout.
 - b. posttraumatic stress disorder.
 - c. learned helplessness.
 - d. victim syndrome.
12. Hostility is characterized by
 - a. patience.
 - b. low levels of aggression.
 - c. distrust of others.
 - d. very few emotional stress reactions.
13. According to your text, the most preventable risk factor for fatal illnesses in the United States is
 - a. alcohol use.
 - b. diet.
 - c. smoking.
 - d. unsafe sex.
14. Eduardo is learning a coping technique. His instructor has told him to alternate between tensing and relaxing his muscles. Which method is he learning?
 - a. Cognitive restructuring
 - b. A behavioral coping method
 - c. Progressive relaxation training
 - d. Stress reaction restructuring
15. The longitudinal quasi-experiment on the relationship between personality and health showed that participants who
 - a. were impulsive were more likely to die from accidents.
 - b. acted conscientiously were more likely to die of heart disease.
 - c. ate more healthily were more likely to get divorced.
 - d. stayed married were more likely to die young.
16. Even though Helen was HIV positive, she believed that her risk of acquiring full-blown AIDS was relatively low. She used active coping strategies to combat psychological distress and anxiety. This, in turn, seemed to improve the functioning of her immune system. Helen probably had
 - a. an emotion-focused coping strategy.
 - b. a disease-prone personality.
 - c. dispositional optimism.

- d. insulation effects.
- 17. Willy is taking sedatives in order to reduce his stress reactions. His family is trying to convince him to use another coping method. What might their reason be?
 - a. Chemical coping methods provide only temporary relief from stress.
 - b. Chemical coping methods can lead to addiction.
 - c. Chemical coping methods will not help Willy feel that he has control over the stressors in his life.
 - d. All of the above
- 18. A good stress-management program includes
 - a. systematic stress assessment.
 - b. goal setting.
 - c. effective plans for coping with stressors.
 - d. All of the above.
- 19. Cognitive restructuring is a(n)
 - a. emotional reaction to stress.
 - b. attempt to change stress-producing thought patterns.
 - c. plan to restructure the use of one's time.
 - d. process of systematic relaxation.
- 20. An example of a person using a behavioral coping strategy is
 - a. Bette, who exercises daily.
 - b. Liang, who uses time management to ensure work is completed.
 - c. Pollyanna, who says to herself, "Everything will be fine."
 - d. Winston, who uses meditation to reduce his need for cigarettes.

Total Correct (See answer key) _____

Sample Quiz 2

Use this quiz to reassess your learning after taking Quiz 1 and reviewing the chapter.

1. Andy has decided to switch careers. He used to be a lawyer but has decided to become an actor. Andy cannot wait to begin his new career. This is an illustration of what kind of situation commonly associated with stress?
 - a. Major life change
 - b. Catastrophic event
 - c. Chronic stress
 - d. Daily hassles
2. Glenda feels that she has had a rotten day. She got a run in her stocking before she left the house, slammed her finger in the car door, forgot to buy cat litter at the grocery store, and just missed a phone call from her boyfriend. Based on this information, what would be her score on the Social Readjustment Rating Scale?
 - a. Low
 - b. Moderate
 - c. High
 - d. Extremely high
3. When Caitlin did poorly on a midterm exam, she berated herself, saying, "You'll never do well. How did you ever get into this school? You'll probably flunk out because you're so stupid! Then you'll probably never be able to get a job." This is an example of
 - a. cognitive restructuring.
 - b. catastrophizing.
 - c. trauma.
 - d. fight-or-flight.
4. It is 2:00 a.m. and Aaron is lost in New York City with no money. His sympathetic nervous system has initiated the fight-or-flight syndrome. What stage of the general adaptation syndrome (GAS) is he in?
 - a. Alarm

- b. Resistance
 - c. Exhaustion
 - d. The fight-or-flight syndrome is not part of the GAS.
5. Corticosteroids, which is released from the adrenal cortex.
- a. indirectly decreases the chance of developing arthritis.
 - b. can damage heart and blood vessels.
 - c. increases the responsiveness of the immune system.
 - d. reduces activation of the sympathetic nervous system.
6. Shane, a veteran, occasionally has flashbacks that are recollections of his experiences in Vietnam. This is a symptom of
- a. generalized anxiety disorder.
 - b. posttraumatic stress disorder.
 - c. the general adaptation syndrome.
 - d. the fight-or-flight syndrome.
7. Oscar has arthritis and high blood pressure. Oscar is in the _____ stage of Selye's general adaptation syndrome (GAS).
- a. acceptance
 - b. alarm reaction
 - c. resistance
 - d. exhaustion
8. When Dr. Crusher went to the computer to explore ideas about the causes of an epidemic, she suddenly could not think. She stared at the computer screen unable to formulate any ideas or even remember information about the illness. Dr. Crusher is experiencing a(n) _____ stress response.
- a. behavioral
 - b. cognitive
 - c. emotional
 - d. problem-focused
9. Which of the following could reduce the impact of a stressor?
- a. Interpreting it as a threat
 - b. Having a social support network
 - c. Feeling an inability to control it
 - d. All of the above
10. Behavioral stress responses include
- a. a change in facial expression.
 - b. feeling nervous.
 - c. ruminative thinking.
 - d. sweating.
11. Which of the following would cause the least stress?
- a. Pop quizzes scheduled by the teacher
 - b. Quizzes prescheduled by the students' unanimous vote
 - c. Quizzes given every Friday
 - d. One quiz per month at an unannounced time
12. The head of human resources knows that the employees have very stressful jobs. One Friday afternoon each month he invites several employees who do not know one another to have lunch and spend the afternoon together. He has
- a. engaged his employees in cognitive restructuring.
 - b. set up a social support network for his employees.
 - c. provided his employees with a sense of control over their stress.
 - d. All of the above

13. _____ is the field that examines the interaction of psychological and physiological processes that affect the body's ability to defend itself against disease.
- Neurology
 - Psychobiology
 - Immunology
 - Psychoneuroimmunology
14. John hasn't declared his major yet and feels that he has no time to think about it because he is overwhelmed by the workload of his general education courses. To cope with the stress and uncertainty, he begins a diary in which he writes quick notes about events, stress, and his reactions. John will probably _____ as a result of his _____.
- improve his immune system functioning; disclosure
 - improve his immune system functioning; behavioral stress response
 - have no effect on his immune system; cognitive stress response
 - have no effect on his immune system; physical coping strategy
15. According to Rosenstock's health-belief model, which of the following would help Birgit quit smoking?
- Perceiving a personal threat from her smoking behavior
 - Realizing that smoking can cause lung cancer
 - Believing that if she quits, she won't get lung cancer
 - All of the above
16. Assume you are reading a science fiction story in which minds are able to visit the government biological bank and select body shells they wish to inhabit, along with physiological system packages. But government leaders have recently decided that budget cuts are necessary and funding for these packages will have to be reduced. If the immune system package is to be downsized, what part of it should *not* be eliminated?
- Corticosteroids
 - Catecholamines
 - Leukocytes
 - The GAS
17. Carrie is a hard-working lawyer. She worries that her busy lifestyle might put her at risk for coronary heart disease. She is *most* at risk if she is also a(n) _____ person.
- impatient
 - hostile
 - competitive
 - assertive
18. Amanda loves chocolate chip cookies. She knows they aren't healthy foods and often thinks about limiting her intake of them or giving them up. However, Amanda has made no plans to change how often she eats them. Amanda is at the _____ stage of readiness.
- precontemplation
 - contemplation
 - preparation
 - maintenance
19. Progressive relaxation training is a _____ coping method.
- cognitive
 - behavioral
 - physical
 - chemical

20. Sayumi is attempting to change her lifestyle to reduce her health risks from her hostility; therefore, Sayumi thinks to herself, "Don't jump to conclusions; they probably didn't mean it like it sounded" instead of, "Those jerks! Who do they think they are?" Sayumi is trying the _____ coping strategy.
- cognitive restructuring
 - emotional
 - physical
 - precontemplation
- Total Correct (See answer key) _____

ANSWERS TO MULTIPLE-CHOICE QUESTIONS

Circle the question numbers you answered correctly.

Sample Quiz 1

- c* is the answer. Often minor daily hassles have a larger impact than one or two major stressors. (see Psychological Stressors)
 - Major life events, either positive or negative, are stressful, but small daily hassles are also stressful.
 - Sometimes the cumulative effect of small but consistent stressors is larger than the effect of one or two major stressors.
 - Even minor stressors alone can add up to major stress reactions.
- d* is the answer. Positive life events (marriage), any type of change (vacation), and consistent daily hassles (listening to a baby cry) are all stressors. (see Psychological Stressors)
- b* is the answer. (see Physical Responses)
 - Resistance is the second stage of the general adaptation syndrome.
 - Exhaustion is the third stage of the general adaptation syndrome.
 - There is no such thing as the adaptation stage.
- b* is the answer. Burnout is a response to chronic stress in which a person becomes more and more irritable, indifferent, and unreliable. (see Linkages: Stress and Psychological Disorders)
 - Behavioral stress responses are changes in the way people look, act, or talk. Aggression, dropping out of school, and strained facial expressions are examples. Mario is experiencing burnout, which is a pattern of physical, psychological, and behavioral stress responses.
 - A disease of adaptation is an illness that occurs in the exhaustion stage of the general adaptation syndrome.
 - Posttraumatic stress disorder is also a combination of physical, psychological, and behavioral stress responses, but it happens after a catastrophic event.
- c* is the answer. Overarousal can reduce creative problem solving, thereby creating a tendency to rely on mental sets and well-rehearsed behaviors. (see Physical Responses)
 - Overarousal decreases performance on nonpracticed tasks.
 - Overarousal can cause thinking to become fuzzy.
 - Overarousal can disrupt information processing.
- a* is the answer. During the resistance stage of the GAS, the symptoms of the alarm reaction subside, but the body's energy is being drained and the immune system compromised. (see Physical Responses)

- b, d.* These are diseases of adaptation indicative of the exhaustion stage of the GAS.
- c.* Changes in heart rate, respiration, and muscle tension are part of the alarm reaction stage of the GAS.
7. *d* is the answer. (see Physical Responses)
- a.* Selye has been criticized for overemphasizing the role of biological factors in the determination of stress responses.
- b, c.* People have commented that Selye did not focus on the role of psychological factors in the determination of stress responses.
8. *b* is the answer. The way that people interpret their stress affects the impact of their stressors. Randy is interpreting his work as a stressor instead of as an opportunity. Melissa is thinking of her work as a vehicle for furthering her career. (see How Stressors Are Appraised)
- a.* Melissa sees her workload in a positive way, so she will not experience as much stress.
- c.* Women are no more prone to stress than men are.
- d.* Randy will experience more stress than Melissa.
9. *c* is the answer. If Julie knows the test will be hard, then she should be better able to deal with it. According to your text, stressors that are predictable have less impact than those that are unpredictable. (see Predictability and Control)
- a.* If Julie is surprised by the format of the test, she will most likely experience more stress.
- b.* If Julie believes she will fail the test, she may feel more stress.
- d.* If Julie doesn't know anyone in the class, she may receive less social support at the time of the test.
10. *b* is the answer. People are unlikely to try to quit smoking unless they have a sense of self-efficacy, the belief that they can quit. (see Health Beliefs and Health Behaviors)
- a, c, d.* All of these are addressed in the question and can be matched to factors identified by Rosenstock. However, Wing will need to believe he can succeed before he will try to quit.
11. *b* is the answer. Posttraumatic stress disorder is a pattern of adverse reactions following a traumatic event. Symptoms include sleep disturbances and feelings of guilt. (see Linkages: Stress and Psychological Disorders)
- a.* Burnout is a reaction to chronic stress. Fenster's problems occurred as a result of one traumatic event.
- c.* Learned helplessness occurs when people learn to believe that nothing they can do will affect their environmental circumstances. It does not apply here.
- d.* This is not a term for a psychological disorder connected with stress.
12. *c* is the answer. People who exhibit hostility are suspicious, resentful, antagonistic, and distrustful of others. Hostility is a risk factor in heart disease. (see Thinking Critically: Does Hostility Increase the Risk of Heart Disease?)
- a, b.* People with hostility are unlikely to be patient and nonaggressive.
- d.* People who exhibit hostility are frequently angry.
13. *c* is the answer. (see Risking Your Life: Health-Endangering Behaviors)
- a, d.* Alcohol abuse and unsafe sex can also lead to major health problems, but neither of these is the most preventable risk factor.
- b.* Diet is important to health, but smoking, alcohol abuse, and unsafe sex are greater risks to health.
14. *c* is the answer. Progressive relaxation training is a physiological coping method in which people learn to completely relax their muscles, thus reducing heart rate and blood pressure. To learn this technique, people are told to alternately tense and relax their muscles in order to better recognize the feelings of relaxation. (see Programs for Coping with Stress and Promoting Health)
- a.* Cognitive restructuring involves replacing catastrophic thoughts with constructive thoughts.

- b.* Behavioral coping methods might involve taking a time-management course. Progressive relaxation training is a physiological coping method.
- d.* There is no such method as stress reaction restructuring.
15. *a* is the answer. People who were impulsive or low on conscientiousness were more likely to die from accidents or violence. (see Focus on Research Methods: Personality and Health)
- b, c, d.* Those who were conscientious were more likely to stay married, eat healthily, and live longer.
16. *c* is the answer. Helen appears to have a disease-resistant personality. One component of this personality is dispositional optimism, the belief or expectation that things will work out positively. (see Stress, Personality, and Gender)
- a.* Pessimists tend to use emotion-focused coping strategies such as denial and avoidance.
- b.* Disease-prone personalities tend to have cognitive styles that focus on negatives.
- d.* This term was not used in describing the connection between personality and the effects of stress.
17. *d* is the answer. Chemical methods of coping provide only temporary relief from stressors, they can be addictive, and they do not provide a sense of control over stressors. People attribute their enhanced sense of well-being to the drug instead of to their own behavior. (see Programs for Coping with Stress and Promoting Health)
18. *d* is the answer. An effective stress-management program includes a systematic stress assessment. You have to know what the problem is before you can solve it. Setting goals helps you decide whether to eliminate the stressor or attempt to reduce the impact of that stressor. Finally, an effective plan must be made in order to deal with the stressors you face. (see Programs for Coping with Stress and Promoting Health)
19. *b* is the answer. Cognitive restructuring involves substituting constructive thoughts for stressful, destructive thoughts. (see Programs for Coping with Stress and Promoting Health)
- a.* Emotional stress reactions include frustration, anger, and depression.
- c.* Time management is important in reducing the stress caused by a tight schedule, but this coping method is behavioral, not cognitive.
- d.* Progressive relaxation is the physiological coping method in which people are taught to completely relax their bodies.
20. *b* is the answer. Time management is an example of a behavioral coping strategy. (see Programs for Coping with Stress and Promoting Health)
- a.* Bette is engaging in a physical coping strategy.
- c.* Pollyanna is engaging in a cognitive coping strategy.
- d.* Winston is using a physical coping strategy.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 1 that you answered correctly.

ANSWERS TO MULTIPLE-CHOICE QUESTIONS

Circle the question numbers you answered correctly.

Sample Quiz 2

1. *a* is the answer. A career switch is a major life event filled with change. Even though Andy is happy, he will have to adjust to his new lifestyle. Changes require adjustment, which is stressful. (see Psychological Stressors)
- b.* Catastrophic events are major and shocking physical or emotional events. Traumatic incidents such as assault and natural disasters fall under this category.
- c.* Andy may eventually experience chronic stress as an actor, but we can't tell that from the story; all we are told is that he is changing careers.

- d.* Andy, like most people, probably experiences daily hassles, but the story illustrates a major life change, not a daily hassle.
2. *a* is the answer. Glenda's day has been filled with small daily hassles. The Social Readjustment Rating Scale measures the stress resulting from *major* life events. Glenda's rating would be low. But remember that small daily hassles can be just as stressful in some cases as major life events. (see Measuring Stressors)
- b, c, d.* The SRRS measures stress resulting from major life events. Glenda has not experienced a major life event, so she has a low score. However, she still has experienced stress.
3. *b* is the answer. Catastrophizing is an overemphasis of the negative consequences of an event. Although Caitlin has done poorly on only one test, she has inflated the negative consequences of that event until she thinks she will never amount to anything. (see Psychological Responses)
- a.* Cognitive restructuring is a cognitive coping method. Positive, constructive thoughts are substituted for negative, destructive thoughts.
- c.* Trauma is a major and shocking physical or emotional experience. Doing poorly on one test is not.
- d.* Fight-or-flight is a term associated with the alarm reaction of the GAS.
4. *a* is the answer. The fight-or-flight syndrome is associated with the alarm reaction of the general adaptation syndrome. (see Physical Responses)
- b, c.* The resistance and exhaustion stages of the GAS are not associated with the fight-or-flight syndrome.
- d.* The fight-or-flight syndrome is part of the alarm reaction of the general adaptation syndrome.
5. *b* is the answer. High levels of corticosteroids are associated with increases in fatty substances that are deposited in arteries and that contribute to coronary heart disease. (see Physical Responses)
- a, c.* Corticosteroids suppresses the functioning of the immune system, thereby promoting illnesses like heart disease, high blood pressure, and arthritis.
- d.* When the sympathetic nervous system is activated, it causes surges of corticosteroids and catecholamines. Corticosteroids does not reduce the activation of the sympathetic nervous system.
6. *b* is the answer. Posttraumatic stress disorder is a pattern of adverse and disruptive reactions following a traumatic event. In rare cases, flashbacks occur. (see Linkages: Stress and Psychological Disorders)
- a.* Generalized anxiety disorder occurs when a person experiences constant emotional arousal with no identifiable cause.
- c.* The general adaptation syndrome is a series of physiological adaptations to stress.
- d.* The fight-or-flight syndrome is caused by an increase in adrenaline in response to a stressor. It prepares the body to either fight or flee.
7. *d* is the answer. Oscar's arthritis and high blood pressure are diseases of adaptation, according to the GAS. He is in the exhaustion stage. (see Physical Responses)
- a.* Acceptance is not one of the stages of the GAS.
- b.* The alarm reaction stage is characterized by the fight-or-flight response.
- c.* Resistance is the stage in which a person isn't feeling physical symptoms of stress. The body's energy is being drained, and levels of corticosteroids are high.
8. *b* is the answer. (see Psychological Responses)
- a.* Behavioral stress responses are changes in appearance, such as shakiness or aggressive actions.
- c.* Emotional stress responses are changes in emotional state, such as fear, anger, irritability, and so on.
- d.* You may have been thinking of problem-focused coping; it is not a stress response, but it is an emphasis on changing or getting rid of a stressor.
9. *b* is the answer. The existence of a social support network can reduce the impact of a stressor. (see Social Support)
- a.* Perceiving a stressor as a threat increases the negative impact of a stressor.

- c. People who believe that they have the ability to control stressors generally experience less stress, even if they cannot control the stressor.
 - d. Only *b* is the answer.
10. *a* is the answer. Facial expressions, shaking hands, and stuttering are examples of behavioral stress responses. (see Psychological Responses)
- b*. Feeling nervous is an emotional stress response.
 - c*. Ruminative thinking is a cognitive stress response.
 - d*. Sweating is a physical stress response.
11. *b* is the answer. When one can predict and control the presence of a stressor, the impact of that stressor is usually reduced. To students, being able to control and predict the occurrence of a quiz is much less stressful than any of the other alternatives. (see Predictability and Control)
- a*. Pop quizzes are not predictable and are therefore more stressful.
 - c*. Even though quizzes given every Friday are predictable, students have no control over the scheduling of such quizzes.
 - d*. One unannounced quiz per month is neither predictable nor controllable.
12. *b* is the answer. By arranging for employees to get together and socialize, the human resources manager has created the potential for a social support network at work. (see Social Support)
- a*. Cognitive restructuring involves substituting constructive thoughts for negative, debilitating thoughts.
 - c*. The head of human resources has not been able to give employees a sense of control over the stressful events at work. But he has provided employees with the beginnings of a social support network.
 - d*. *b* is the answer.
13. *d* is the answer. Psychoneuroimmunology is the study of the interaction of psychological and physiological processes that affect the body's ability to defend itself against disease. (see Stress, Illness, and the Immune System)
- a*. Neurology is the study of the nervous system.
 - b*. Psychobiology is the study of the biological factors that underlie mental processes and behavior.
 - c*. Immunology is the study of the physiological processes that affect the body's ability to defend itself against disease.
14. *a* is the answer. Disclosure, even anonymously, has been shown to improve immune system functioning. (see Stress, Illness, and the Immune System)
- b*. John is expressing pent-up thoughts and feelings, which is disclosure. A behavioral stress response is a reaction like aggression, alcohol abuse, or avoidance of the stressful situation.
 - c, d*. John is disclosing and it is likely to have a positive effect on his immune system.
15. *d* is the answer. (see Health Beliefs and Health Behaviors)
16. *c* is the answer. Leukocytes are an important component of the immune system; they serve as the body's defense system against foreign toxins. (see Stress, Illness, and the Immune System)
- a*. Corticosteroids are hormones released by the adrenal gland in reaction to persistent stress. This is not part of the immune system.
 - b*. Catecholamines are hormones released by the adrenal gland when the sympathetic nervous system is activated in initial reactions to stress. This is not part of the immune system.
 - d*. The GAS is a sequence of physical responses to stress. It is not part of the immune system.
17. *b* is the answer. A link has been identified between hostility and risk for heart disease and heart attack. (see Thinking Critically: Does Hostility Increase the Risk of Heart Disease?)

- a, c, d.* All of these may be features of a person with a busy lifestyle, but none has been definitely linked with coronary heart disease.
18. *b* is the answer. Being aware of a problem behavior and thinking of changing are part of the contemplation stage of readiness. (see Changing Health Behaviors: Stages of Readiness)
- a.* Precontemplation is the stage when a person does not perceive a problem and isn't considering change.
- c.* Preparation involves making plans.
- d.* Maintenance occurs after a person has successfully made a behavior change and kept it up for more than a few months.
19. *c* is the answer. Progressive relaxation is a technique used to relax the muscles, leading to reduced heart rate and blood pressure. (see Programs for Coping with Stress and Promoting Health)
- a.* Cognitive coping methods include cognitive restructuring.
- b.* Behavioral coping methods include time-management improvements.
- d.* Chemical coping methods fall under the physical coping strategy category and include the use of sedatives.
20. *a* is the answer. Sayumi is replacing unconstructive thoughts with more constructive ones. (see Programs for Coping with Stress and Promoting Health)
- b.* Social support is an example of an emotional coping strategy.
- c.* Physical coping strategies change bodily processes through drugs, exercise, meditation, and other means.
- d.* Precontemplation is a stage of readiness, not a coping strategy.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 2 that you answered correctly.

For each question you answered correctly, circle its number. (Quiz 1 numbers are not shaded; Quiz 2 numbers are shaded.) Are there patterns in the types of questions or the topics you got wrong that could direct your further study? Did you improve from Quiz 1 to Quiz 2?

CHAPTER 14

Personality

MULTIPLE-CHOICE QUESTIONS

Sample Quiz 1

1. The _____ approach to personality assumes that the unconscious plays a major role in determining behavior.
 - a. trait
 - b. social-cognitive
 - c. psychodynamic
 - d. humanistic
2. The following is a conversation going on in someone's head:
X: I am so mad that I could bash that person's skull in. I cannot believe he did that.
Y: You know you are not supposed to hurt other people.
Z: Why not tell him that his behavior is inappropriate so that he won't repeat it?

- X is the _____, Y is the _____, and Z is the _____.
- id; ego; superego
 - ego; id; superego
 - superego; id; ego
 - id; superego; ego
- Tom finds his wife stupid and sexually unattractive but doesn't tell her about these feelings. Instead, he criticizes his secretary for making mistakes and makes derogatory remarks about *her* appearance. This is an example of which defense mechanism?
 - Rationalization
 - Displacement
 - Reaction-formation
 - Projection
 - Eduardo believed that his poetry was not simply an expression of his personal feelings but rather a part of his being that represented the deepest feelings of all people. Eduardo's notion is similar to
 - Jung's collective unconscious.
 - Hippocrates's humors.
 - Gray's BAS.
 - Allport's central traits.
 - The Oedipus complex is part of the _____ stage of psychosexual development.
 - oral
 - anal
 - phallic
 - genital
 - Object relations are part of _____ theory.
 - contemporary psychodynamic
 - trait
 - humanistic
 - social-cognitive
 - Central traits
 - were suggested by a social-cognitive theorist to explain behavior.
 - organize and control behavior across many situations.
 - are more situation-specific than are secondary traits.
 - are seen in growth-oriented individuals.
 - Toni describes her best friend as intelligent, caring, extraverted, and lots of fun to be with. Which type of theorist would use the same type of description that Toni does?
 - Trait
 - Social-cognitive
 - Psychodynamic
 - Humanistic
 - Which of the following is an example of a person exhibiting a secondary trait?
 - Amy, who is obnoxious and opinionated only when debating politics
 - Arnold, whose entire life is devoted to ridding the world of thieves, murderers, and drug dealers
 - Cathy, who usually sees the positive side of events
 - Dave, who loves to help those less fortunate than himself
 - Lauren, who normally is easy-going and friendly, was anxious and suspicious when she met the woman responsible for the break-up of her marriage. This extreme change in Lauren's personality would best be explained by which theorist?
 - Adler
 - Mischel
 - Maslow
 - Horney

11. The best evidence that the dimensions of the big-five factors may represent the basic components of personality is that
 - a. they were derived by using factor analysis techniques.
 - b. some version of the big-five factors reliably appears in many countries and cultures.
 - c. they do an excellent job of describing people.
 - d. identical twins are no more alike in general temperament than are nonidentical twins.
12. The belief that behavior can be situation-specific is a main argument *against* which approach to personality?
 - a. Psychodynamic
 - b. Social-cognitive
 - c. Humanistic
 - d. Trait
13. Perceived self-efficacy is
 - a. our collection of learned expectancies for success in given situations.
 - b. the efficiency with which we resolve unconscious conflicts.
 - c. a secondary trait.
 - d. a role of the ego.
14. Rotter's expectancy theory is part of the _____ approach to personality.
 - a. trait
 - b. humanistic
 - c. social-cognitive
 - d. psychodynamic
15. At home, Rebecca's daughter is very polite. Rebecca is horrified when she finds out that her daughter is rude at school. She suggests that the teacher begin rewarding her daughter for being polite. Rebecca is taking which approach to personality?
 - a. Psychodynamic
 - b. Social-cognitive
 - c. Humanistic
 - d. Trait
16. A deficiency orientation occurs when people
 - a. make do with less than perfect conditions.
 - b. focus on things they do not have.
 - c. attempt to fulfill their potentials.
 - d. have a trait missing from their personality.
17. Kareem and Burke are having a heated argument over which theory of personality is correct. Kareem says that Burke's emphasis on learning reduces humans to robots and ignores their perceptions, values, and beliefs. Kareem is probably a _____ theorist, and Burke is a _____ theorist.
 - a. social-cognitive; psychodynamic
 - b. humanistic; psychodynamic
 - c. trait; social-cognitive
 - d. humanistic; social-cognitive
18. Teddy had always been a well-adjusted child, but when he was thirteen, he got into trouble a few times. What is a likely prediction for Teddy's personality at age eighteen?
 - a. Teddy's personality was affected by hormonal changes during puberty, and he will continue to exhibit troubled behavior.
 - b. Teddy's personality was affected by the problems in puberty and will be unstable.
 - c. Teddy will probably be a well-adjusted adult because he was well-adjusted during most of his childhood.
 - d. No predictions can be made about Teddy's personality at age eighteen.
19. Which of the following would a humanistic psychologist use most frequently to assess personality?
 - a. Behavioral observations
 - b. Objective tests

- c. Assessments of physiological activity
 - d. Personal interviews
20. Tameka shows her clients a series of ambiguous pictures she painted and asks them to tell a story about each picture. Tameka hopes that her _____ personality test will uncover some of the unconscious thoughts of her clients.
- a. multiphasic
 - b. objective
 - c. projective
 - d. social-cognitive
- Total Correct (See answer key) _____

Sample Quiz 2

Use this quiz to reassess your learning after taking Quiz 1 and reviewing the chapter.

1. Lydia, a married woman, is incredibly attracted to her physician. Her _____ decides that the only way to see her doctor more often is to have more frequent physicals and have even the slightest symptom investigated immediately.
 - a. id
 - b. ego
 - c. superego
 - d. eros
2. Oliver thinks that everyone in all his lecture courses is cheating. Oliver probably feels like cheating himself. This is an example of which defense mechanism?
 - a. Creativity
 - b. Reaction-formation
 - c. Rationalization
 - d. Projection
3. Fixation occurs when
 - a. psychosexual conflicts are not resolved.
 - b. we use defense mechanisms to relieve anxiety.
 - c. the rewards in a given situation fix our behaviors.
 - d. our progress toward self-actualization is blocked at some stage.
4. Use the following conversation to answer the question: **Joe:** I don't think we should hire him. I saw him in a barroom brawl a few months ago. Why hire someone who is going to be aggressive in any given situation?-- **Kim:** His MMPI scores indicate that he isn't prone to violence.-- **Richard:** His self-concept may not include violence.--- **Erika:** Joe, how do you know that he's always going to be aggressive? Maybe the guy was just under stress at the time. Maybe he knows from past experience that a good fist fight relieves tension.
Which of the following approaches is *not* represented in the above conversation?
 - a. Social-cognitive
 - b. Psychodynamic
 - c. Humanistic
 - d. Trait
5. Use the following conversation to answer the question: **Joe:** I don't think we should hire him. I saw him in a barroom brawl a few months ago. Why hire someone who is going to be aggressive in any given situation?-- **Kim:** His MMPI scores indicate that he isn't prone to violence.-- **Richard:** His self-concept may not include violence.--- **Erika:** Joe, how do you know that he's always going to be aggressive? Maybe the guy was just under stress at the time. Maybe he knows from past experience that a good fist fight relieves tension.
Which two speakers agree with the trait approach to personality?
 - a. Joe and Richard
 - b. Erika and Kim
 - c. Joe and Kim

- d. Richard and Erika
6. Nine-year-old Cass has just bounded into the room with her latest artistic creation. She bubbles on and on about her friends at school and how much she likes her teacher. Which psychosexual stage of development is she most likely in?
- Oral
 - Anal
 - Phallic
 - Latency
7. Dr. Lebryk believes Jack's romantic relationships are brief and unhappy because Jack had an anxious insecure attachment to his mother. Dr. Lebryk is most likely a(n) _____ theorist.
- big five
 - social-cognitive
 - humanistic
 - object relations
8. You describe your friend as outgoing, eccentric, generous, emotional, talkative, impulsive, and easygoing. Gordon Allport would say you have listed your friend's
- central traits.
 - secondary traits.
 - level of perceived self-efficacy.
 - level of externality.
9. Charlie acted the way he did because he saw life as a continual struggle. He felt that the world was against him and that everything he tried to do would be difficult and painful. This description of Charlie best fits with which approach to personality?
- Psychodynamic
 - Trait
 - Social-cognitive
 - Humanistic
10. One of the criticisms of the humanistic approach is that it
- concentrates too much on what human beings have in common.
 - is naive, romantic, and unrealistic.
 - puts too much emphasis on explaining personality.
 - puts undue emphasis on instincts.
11. According to Rogers, human behavior is motivated by
- unknown forces.
 - the pursuit of material goods.
 - the actualizing tendency.
 - a preoccupation with sex.
12. Which of the following is *not* a criticism of the trait theories of personality?
- They describe behavior better than they explain it.
 - They create descriptions that may be too general.
 - They ignore situational influences on behavior.
 - They place too much emphasis on the unconscious.
13. The learning process is most central to which personality theory?
- Psychodynamic
 - Trait
 - Social-cognitive
 - Big five
14. Joe is an internal, according to Rotter's expectancy theory of personality. Therefore, you would expect Joe to
- ignore physical symptoms of illness.
 - work on a factory assembly line.

- c. take a self-paced course at school.
 - d. All of the above
15. According to Bandura, a child could _____ through observational learning.
- a. learn to be truthful
 - b. learn how to con Dad into giving up the car
 - c. learn how to be assertive
 - d. All of the above
16. Martin was in his room reading contentedly when his father came in and told him that he was a bookworm and that if he were a real boy, he would be outside playing soccer. Martin's father may be creating a(n) _____, according to Rogers.
- a. deficiency orientation
 - b. fixation
 - c. interdependent self-system
 - d. condition of worth
17. Grace tries not to stand out from the crowd. Not only does she describe herself in terms of her place in her family and work groups, but she also feels happiest when her interactions with her groups have gone well. Grace most likely
- a. has an independent self-system.
 - b. has an interdependent self-system.
 - c. is an internal.
 - d. is an external.
18. A projective test is usually
- a. reliable.
 - b. valid.
 - c. easy to score.
 - d. None of the above
19. Mark has just looked through a series of pictures and described what he thinks are the stories underlying the scenes. Mark has just
- a. taken an objective test.
 - b. taken the MMPI.
 - c. taken a projective test.
 - d. been interviewed.
20. Mimi wants to determine her client's level of depression using an objective test. Which of the following should be true of the measure?
- a. The stimuli should be ambiguous.
 - b. The tester should interpret the numerical score based on norms.
 - c. The unstructured format will allow for reflection of an individual's level of depression.
 - d. All of the above

Total Correct (See answer key)

ANSWERS TO MULTIPLE-CHOICE QUESTIONS

Circle the question numbers you answered correctly.

Sample Quiz 1

1. *c* is the answer. The psychodynamic approach assumes that personality is determined by unconscious mental processes. (see Structure and Development of Personality)
 - a.* The trait approach assumes that personality is a stable combination of traits or type characteristics.
 - b.* The social-cognitive approach assumes that personality is essentially the same thing as behavior. The social-cognitive approach would also say that we have expectancies based on previous experience.
 - d.* The humanistic approach assumes that personality is a product of each person's values, beliefs, and perceptions.
2. *d* is the answer. X wants to be aggressive. Y knows all the rules about what behaviors one should and should not display. Z will try to obey the rules of society as well as satisfy the id and superego. (see Structure and Development of Personality)
3. *b* is the answer. Tom is displacing his feelings from the original source to an alternative source, his secretary. (see Structure and Development of Personality)
 - a.* Rationalization is an attempt to explain away behavior. If this were the case, Tom might tell himself that all marriages have their low spots.
 - c.* Reaction-formation guides behavior in the direction opposite that of the unwanted impulse. If this were the case, Tom would shower his wife with attention and affection, telling her how intelligent and beautiful he thought she was.
 - d.* Projection is seeing unwanted impulses and desires in others. If this were the case, Tom might start noticing that his friends treat their wives very badly.
4. *a* is the correct answer. Jung defined the collective unconscious as the memories that each of us inherits from our human and nonhuman ancestors. So Eduardo's poetry would be influenced by that part of him that was connected to the feelings of all people who had ever lived. (see Variations on Freud's Personality Theory)
 - b.* Hippocrates suggested that personality was associated with differential amounts of four different humors, or bodily fluids. This would not explain how the feelings of all people wound up in Eduardo's poetry.
 - c.* Gray's Behavioral Approach System, or BAS, focuses on the sensitivity of the individual's brain to rewards.
 - d.* Allport's central traits focus on traits that describe individuals such that the individual is differentiated from others, not similar to others.
5. *c* is the answer. The Oedipus complex occurs during the phallic stage. According to Freud, boys desire their mothers and wish to kill their fathers. This is similar to the plot of the Greek tragedy *Oedipus Rex*. (see Structure and Development of Personality)
 - a.* The oral stage occurs during the first year of life, when a child derives pleasure mainly from the mouth.
 - b.* The anal stage occurs during the second year of life, when a child derives sexual pleasure mainly from the anal area.
 - d.* The genital stage lasts from puberty onward. The pleasure found in relationships during this stage is dependent upon the resolution of conflicts at earlier stages.
6. *a* is the answer. Object relations theorists study the relationship between people and significant objects. (see Contemporary Psychodynamic Theories)
 - b.* Trait theorists study dispositions.
 - c.* Humanistic theorists focus on people's perceptions of the world and their tendency toward reaching their potential.
 - d.* Social-cognitive theorists focus on behaviors and learned thought patterns, which they believe influence personality.

7. *b* is the answer. According to Allport's trait theory, about seven central traits guide our behavior in many situations. (see Allport's Trait Theory)
 - a.* Central traits were proposed by Allport, who was a trait, not a social-cognitive theorist.
 - c.* Secondary traits are more situation-specific than are central traits.
 - d.* Growth orientation is a humanistic concept proposed by Maslow.
8. *a* is the answer. A trait theorist would describe a person in terms of such stable characteristics. (see The Trait Approach)
 - b.* A social-cognitive theorist would describe a person in terms of behaviors and thought patterns.
 - c.* A psychodynamic theorist would discuss the underlying unconscious conflicts that are responsible for a person's behavior.
 - d.* A humanistic theorist would describe a person's perception of reality, values, and beliefs.
9. *a* is the answer. A secondary trait, according to Allport, is one that is specific to certain situations. (see Allport's Trait Theory)
 - b.* Arnold has a trait that affects his whole life; this would not be a secondary trait, but a central trait.
 - c, d.* Cathy sounds like she is optimistic in most situations and Dave sounds like he is often helpful; therefore, these are not secondary traits.
10. *b* is the answer. Mischel says that to describe a person's behavior, we need to know about the person's thoughts, perceptions, and expectations, as well as the features of the situation. Lauren was probably very hurt by this woman, and she would therefore think and act with anxiety and suspicion, befitting her thoughts and expectations about the situation of meeting the "other" woman. (see Prominent Social-Cognitive Theories)
 - a.* Adler, a neo-Freudian, would have spoken of Lauren in terms of her drive for fulfillment as a person. This approach would not explain her sudden change in personality.
 - c.* Maslow, a humanistic theorist, believed that self-actualization was a human need. His ideas would not adequately explain the shift in Lauren's personality in this situation.
 - d.* Horney, a neo-Freudian, concentrated on cultural factors that affected personality. This would not explain Lauren's sudden change in personality when meeting the "other" woman.
11. *b* is the answer. If these factors appear in many situations in many countries and cultures, this suggests that they are universal and not just researchers' wishful thinking. (see The "Big-Five" Model of Personality)
 - a.* Factor analysis is the basic statistical technique that trait theorists use to cluster similar traits. Its use does not indicate evidence.
 - c.* That traits describe people rather than explain them is one of the criticisms of the approach.
 - d.* This statement is false. Identical twins are more alike in general temperament than fraternal twins are. But this statement provides no evidence for the big-five model.
12. *d* is the answer. Trait theorists argue that behavior is a reflection of consistent and stable traits and that environmental or situational factors do not determine behavior. (see The Trait Approach)
 - a.* Psychodynamic theorists have been criticized for adhering to Freud's emphasis on the unconscious and his use of patients' reports as a basis for psychosexual development theory. Freud was also accused of being sexist. But the belief in situation-specific behavior does not detract from the psychodynamic theory.
 - b.* Social-cognitive theorists have been accused of overemphasizing overt behavior and the environmental factors of reward and punishment and not attending enough to the individual's perceptions, feelings, and thoughts.
 - c.* Humanistic concepts are difficult to measure, more descriptive than explanatory, and naive since they are so optimistic about the nature of men and women.
13. *a* is the answer. According to Bandura, a social-cognitive theorist, our learned expectations for success can influence our behavior. (see Prominent Social-Cognitive Theories)

- b.* Psychodynamic theorists, not cognitive behavioral theorists, focus on unconscious mental processes.
 - c.* Perceived self-efficacy is a social-cognitive phenomenon, not a trait or secondary trait.
 - d.* The ego is a psychodynamic concept, not a social-cognitive concept.
- 14. *c* is the answer. Rotter's expectancy theory is part of the social-cognitive approach. Rotter proposed that internals believe they control events and that externals believe that others (fate, other people, luck) control events. (see Prominent Social-Cognitive Theories)
 - a.* Expectancies are not a trait or type, both of which are the foundation of the trait approach.
 - b.* The humanistic approach doesn't emphasize expectancies in the development of personality.
 - d.* Psychodynamic theories do not emphasize expectancies; they tend to focus on unconscious mental processes.
- 15. *b* is the answer. Rebecca is probably a social-cognitivist. She believes that behavior and thoughts about behavior are shaped by the presence of rewards and punishments in the environment. (see Roots of the Social-Cognitive Approach)
 - a.* A psychodynamic theorist would want to find out what the daughter's unconscious thoughts and feelings were before suggesting a corrective measure.
 - c.* A humanistic theorist would probably want to know how the daughter perceives the situation at school.
 - d.* A trait theorist would not believe that rewards and punishments would be effective and might think that Rebecca's daughter had a secondary trait to be impolite at school.
- 16. *b* is the answer. A deficiency orientation, according to Maslow, occurs when individuals focus on what they do not have instead of on what they do have. (see Prominent Humanistic Theories)
 - a.* If people focus on or derive satisfaction from what they have, they have a growth orientation.
 - c.* Humanistic theorists assume that we all attempt to fulfill our potentials.
 - d.* A deficiency orientation is a humanistic concept that is not related to traits.
- 17. *d* is the answer. Kareem is a humanistic theorist because he thinks that values, beliefs, and perceptions of reality influence personality. Burke follows the social-cognitive approach, which has been accused of viewing people as machines that can be programmed using only rewards and punishments. (see Prominent Humanistic Theories)
 - a, b, c.* Social-cognitive theorists tend not to focus on people's values, beliefs, or perceptions of the world. Psychodynamic and trait theorists have not been accused of ignoring people's values or beliefs, nor do they view people as machines controlled by rewards and punishments.
- 18. *c* is the answer. Longitudinal studies provide support for the idea that relatively accurate predictions can be made about an individual's personality as an adult on the basis of information about that person's temperament as a child. (see Focus on Research Methods: Longitudinal Studies of Temperament and Personality)
 - a, b.* There is no evidence that hormonal changes or problems during puberty will negatively affect an individual's personality.
 - d.* *c* is the answer; predictions can be made, based on information about childhood temperament.
- 19. *d* is the answer. Those who take a humanistic view of personality believe that everyone sees a reality that is unique. Therefore, interviews, during which people can explain their points of view, would be the best method of assessment. (see Assessing Personality)
 - a.* A humanistic theorist would say that one cannot interpret someone's behavior without knowing that person's interpretation or perception of reality.
 - b.* An objective test assumes that people have the same general interpretation of the questions on it. If this were not the case, the questions could not be used to compare one person to another. Humanistic views assume that each person's view of anything, including a true-false or multiple-choice question, is unique.

- c. Humanistic theorists do not depend on physiological data in personality assessment; they are more interested in conscious experience.
20. c is the answer. A projective test uses ambiguous stimuli to allow the taker to project unconscious conflicts and desires onto the test. If the picture of two people is unclear enough, for example, a person who has trouble with authority might make up a story about a person getting a reprimand. (see Projective Tests)
- a. You may have been thinking of the Minnesota Multiphasic Personality Inventory (MMPI), which is an objective test.
- b. Objective tests have specific statements or questions to be read and responded to by the test taker.
- d. Social-cognitive theorists would not use ambiguous stimuli to test for personality. If they used a personality test at all, it would be one that looked for generalized expectancies or ideas about the self.
- Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 1 that you answered correctly.

Sample Quiz 2

1. b is the answer. Lydia's ego has devised a solution that will let her spend more time with a man she is attracted to (thereby satisfying the id) without breaking the rules of society or doing something that the superego would disapprove of. (see Structure and Development of Personality)
- a. The id wants to have sex with the doctor and does not particularly care what rules are broken.
- c. The superego would tell Lydia that she is married and cannot have sex with anyone but her husband.
- d. Eros is the aggregate of life instincts.
2. d is the answer. Oliver is projecting his unwanted impulses onto other people. (see Structure and Development of Personality)
- a. Creativity is not a psychodynamic defense mechanism.
- b. Reaction-formation guides behavior in the direction opposite to that of the unwanted impulse. If Oliver made sure that he was extremely honest in all situations, this would be the correct answer.
- c. Rationalization is an attempt to make your own behavioral actions or mistakes seem reasonable.
3. a is the answer. Fixation occurs when we do not resolve psychosexual conflicts during development. For example, according to Freud, those who are weaned too early may engage in oral activities such as smoking, excessive talking, or overeating. (see Structure and Development of Personality)
- b. We use defense mechanisms to relieve anxiety, but this is not a fixation.
- c. Fixation is not a part of behavioral theory.
- d. Fixation is not part of humanistic theory.
4. b is the answer. Psychodynamic views of personality are not represented by anyone. (see Variations on Freud's Personality Theory)
5. c is the answer. Joe assumes that the man in question will always be aggressive. Trait theorists assume that people have several traits that will be present in many different situations. Kim is talking about the MMPI, a personality test developed by trait theorists. (see The Trait Approach)
- a. Richard agrees with humanistic theorists.
- b. Erika agrees with social-cognitive theorists.
- d. Richard agrees with humanistic theorists, while Erika agrees with social-cognitive theorists.
6. d is the answer. The latency period lasts from about age five until puberty. During this time, a child focuses on education and social development. (see Structure and Development of Personality)
- a. The oral stage occurs during the first year or so of life.
- b. The anal stage occurs during the second year or so of life.
- c. The phallic stage occurs during the third to fifth years of life.

7. *d* is the answer. Many current psychodynamic psychologists focus on object relations. Object relations theory suggests that people's relations to the mother or other primary caregivers shape a person's thoughts about social relationships later in life. Some research shows that early attachment styles are related to current relationship quality. (see Contemporary Psychodynamic Theories)
 - a.* A big five theorist would suggest that one of five traits is influencing Jack's troubles.
 - b.* A social-cognitive theorist would probably hypothesize that Jack expects to fail or that Jack is being rewarded somehow for his present behavior.
 - c.* A humanistic theorist would emphasize Jack's perceptions, not his attachment to his mother.
8. *a* is the answer. Most people can describe someone using about seven labels. Allport called these central traits. (see Allport's Trait Theory)
 - b.* Allport also thought we had secondary traits, which are more tied to a situation. For example, a person who bluffs when playing cards might not bluff in other social situations.
 - c, d.* Perceived self-efficacy and expectancies (internal versus external) are social-cognitive concepts.
9. *d* is the answer. The humanistic approach maintains that the way people perceive and interpret the world forms their personalities and guides their behavior. (see Prominent Humanistic Theories)
 - a.* The psychodynamic approach focuses on the struggle between unconscious impulses and society's rules.
 - b.* The trait approach describes personality as a combination of stable internal characteristics that people consistently display.
 - c.* The social-cognitive approach views personality as an array of behaviors that people acquire through learning and display in particular situations.
10. *b* is the answer. Because the humanistic approach suggests that all people are inherently good and growth-oriented, it has been criticized for being overly optimistic and unrealistic. (see Evaluation of the Humanistic Approach)
 - a.* The humanistic approach concentrates on the differences among individuals to understand personality.
 - c.* Another criticism of the humanistic approach is that it seems to do a better job of describing personality than of explaining it.
 - d.* The humanistic approach does not emphasize instincts. You might be thinking of the psychodynamic approach.
11. *c* is the correct answer. Rogers says we have an innate inclination toward growth and fulfillment. (see Prominent Humanistic Theories)
 - a.* If human behavior is said to be due to unknown forces, then no theory exists.
 - b.* This is part of Maslow's idea of deficiency orientation—that self-actualization is blocked by a preoccupation with material goods.
 - d.* A preoccupation with sex as a motivation for human behavior would fit more with Freud's idea of the id.
12. *d* is the answer. Trait theories do not emphasize the unconscious as psychodynamic theories do. (see Evaluation of the Trait Approach)
 - a.* Traits are much better at describing than explaining behavior.
 - b.* Many trait descriptions seem to fit a large number of people, thus reducing their value for describing a given person.
 - c.* Trait descriptions do not explain situational influences on behavior. Trait theories imply stable behavior, driven by traits, in any situation.
13. *c* is the answer. The social-cognitive approach is based on the assumption that people learn how to think and act. (see Roots of the Social-Cognitive Approach)
 - a.* The psychodynamic approach focuses on the influence of unconscious mental processes on personality.

- b.* The trait approach attributes much of personality to inherent characteristics; it does not emphasize learning as much as the cognitive-behavioral approach does.
- d.* The big five model is an example of a trait theory.
14. *c* is the answer. Joe would be most likely to take a self-paced course because he would prefer being in control of his work pace. (see Prominent Social-Cognitive Theories)
- a, b.* Joe would probably not ignore physical symptoms of illness or work very well on an assembly line. Externals would be more likely to exhibit these types of behavior.
- d.* *c* is the answer.
15. *d* is the answer. According to Bandura, we can learn new behaviors, learn to inhibit behaviors, and learn how to prompt or facilitate behaviors through observational learning. (see Prominent Social-Cognitive Theories)
16. *d* is the answer. According to Rogers, parents may create a condition of worth when they lead a child to believe that his worth depends on displaying the right behaviors. In effect, Martin's father was suggesting that he would love Martin more or be more proud of him if Martin were doing "real" boy activities like playing soccer, rather than reading. (see Prominent Humanistic Theories)
- a.* A deficiency orientation is another humanistic concept, but it occurs when a person focuses on what is missing instead of on growth or satisfaction with current possessions.
- b.* A fixation will occur, according to Freud, if a person does not resolve conflicts at each stage of psychosexual development. Fixations are basically unrelated to parental reprimands.
- c.* Interdependent self-systems are more common in collectivist cultures, where one's place in groups is emphasized.
17. *b* is the answer. People with an interdependent self-system see themselves as a fraction of a whole. They tend not to be happy when singled out for attention, even if it is for personal achievement. (see Linkages: Personality, Culture, and Human Development)
- a.* People with an independent self-system emphasize personal achievement rather than their place in a group.
- c.* This relates to Rotter's expectancy theory. Internals believe that they control events through their own efforts.
- d.* This is part of Rotter's expectancy theory. Externals believe that external forces control events.
18. *d* is the answer. Projective tests involve presenting a subject with an unstructured and ambiguous stimulus. Personality is supposedly reflected in the subject's response. Because the tasks are unstructured, they tend to be relatively difficult to score, unreliable, and not as valid as objective tests. (see Projective Tests)
19. *c* is the answer. Mark has just taken a projective test, most likely the Thematic Apperception Test. (see Projective Tests)
- a, b.* An objective test is a paper-and-pencil test. Answers are written, not explained aloud, by the respondent. The MMPI is an objective test.
- d.* Interviews usually revolve around either structured or unstructured questions, not around ambiguous stimuli such as pictures and inkblots.
20. *b* is the answer. A person's score on an objective test is more meaningful if it can be compared to the average person. If a person receives a 9, for example, on a test of depression, we don't know if that is cause for concern unless we know that a 5 is an average score. (see Objective Tests)
- a, c.* Ambiguous stimuli and an unstructured format are part of a projective test.
- d.* Only *b* is the answer.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 2 that you answered correctly.

For each question you answered correctly, circle its number. (Quiz 1 numbers are not shaded; Quiz 2 numbers are shaded.) Are there patterns in the types of questions or the topics you got wrong that could direct your further study? Did you improve from Quiz 1 to Quiz 2?

CHAPTER 15

Psychological Disorders

MULTIPLE-CHOICE QUESTIONS

Sample Quiz 1

1. The impaired functioning criterion is most associated with which approach to defining abnormality?
 - a. Statistical infrequency
 - b. Psychopathological
 - c. Norm violation
 - d. Practical
2. Encouraging conformity is associated with which approach to defining normality?
 - a. Practical
 - b. Norm violation
 - c. Statistical infrequency
 - d. Both (b) and (c)
3. According to the _____ model, disorders are evidence of an obstruction in the self-actualization process.
 - a. humanistic
 - b. neurobiological
 - c. psychopathological
 - d. perceptual
4. Zelda's doctor told her that she has a genetic predisposition for depression, but that her recent job stress has brought on her latest episode of depression. Zelda's doctor takes the _____ approach to explaining Zelda's depression.
 - a. sociocultural
 - b. neurobiological
 - c. diathesis-stress
 - d. humanistic
5. The DSM-IV lists five axes for diagnosticians to use in evaluating people. Which of the following is *not* covered in one of the axes?
 - a. Major psychological disorder description
 - b. Physical condition
 - c. Stress level
 - d. Social status
6. Kat has dropped out of school. She cannot attend class because the thought of leaving her apartment leaves her feeling nauseated, anxious, and faint. Her symptoms suggest that she
 - a. suffers from agoraphobia.
 - b. has a phobia about classrooms.
 - c. has panic attacks.
 - d. has test anxiety.
7. Laurence is a psychotherapist. One of his patients, Heidi, complains of being very shy and lonely. She also says that she has a very intense need to touch repeatedly all four walls of any room she has never been in before. Laurence tells Heidi that she learned this compulsive behavior so that she could delay immediate social contact with anyone in the room, thereby avoiding the anxiety caused by her extreme shyness. Laurence adheres to the _____ model of abnormal behavior.

8. Sergio, a psychiatric intern, has just completed an evaluation of his new patient by using DSM-IV. Read his evaluation and find what is missing: "The patient is experiencing major depressive disorder, has a dependent personality, has had very minor stress in the past few months, and is in good physical health."
 - a. Axis I
 - b. Axis II
 - c. Axis IV
 - d. Axis V
9. An excessive and unwarranted fear of doorways would be considered
 - a. a specific phobia.
 - b. a social phobia.
 - c. agoraphobia.
 - d. panic disorder.
10. A conversion disorder is characterized by
 - a. functional impairment of a limb or sensory ability with no apparent physical cause.
 - b. severe pain with no apparent cause.
 - c. a constant fear of becoming seriously ill.
 - d. frequent vague complaints of physical symptoms.
11. Tomas has been suffering from severe chest pain for the past few weeks. His doctor has run extensive tests but can find no physical problem. Tomas may
 - a. have a pain disorder.
 - b. have hypochondriasis.
 - c. have paranoia.
 - d. suffer from somatization disorder.
12. "Massive repression of unwanted impulses or memories is responsible for dissociative disorders," is most likely a quote from a _____ theorist.
 - a. social-cognitive
 - b. humanistic
 - c. psychodynamic
 - d. sociocultural

13. Nuwanda and a classmate are talking when Mary approaches and calls Nuwanda "Paul." Although Nuwanda explains that he's from Dallas, Mary convincingly argues that he is Paul, her next-door neighbor in Chicago for twenty years. Nuwanda's identification card confirms that his name is Paul, but he insists that he has no memory of living in Chicago or of being called Paul. Nuwanda/Paul most likely has
 - a. dissociative amnesia.
 - b. dissociative fugue.
 - c. a conversion disorder.
 - d. schizophrenia.
14. For the past three months, Beth has been sleeping twelve to sixteen hours a day and has gained thirty pounds. Gail can barely sleep at all and has lost fifteen pounds without trying; she just does not want to eat. Both women could be suffering from
 - a. obsessive-compulsive disorder.
 - b. major depressive disorder.
 - c. hyperchondriasis.
 - d. hypochondriasis.
15. Pam noticed during their daily tutoring sessions that Enya seemed unhappy for about a week, then happy for the next week. Sometimes the moods lasted longer, but Enya never settled into sadness or happiness for more than a few weeks at a time. Enya consulted a therapist, who suggested that since her mood swings were neither extreme nor debilitating, she most likely was experiencing
 - a. depression.
 - b. cyclothymic disorder.
 - c. dysthymic disorder.
 - d. mania.
16. Sam displays the negative symptoms of schizophrenia when
 - a. in his delusions, he thinks that he is being programmed to stop behaviors in others.
 - b. he claims he is another person named Harry and acts totally unlike himself.
 - c. he completely lacks emotional responses to anything he experiences.
 - d. he keeps thinking he sees bugs moving all around him.
17. Juan has been diagnosed with schizophrenia. He is positive that all the students sitting around him during a test are cheating by reading his thoughts. Juan is experiencing
 - a. delusions.
 - b. hallucinations.
 - c. obsessions.
 - d. loose associations.
18. Sean's roommate could be very charming, but he continually borrowed money without returning it and Sean often caught him telling lies. Sean finally moved out when his roommate borrowed his car, got into a serious accident, and then wondered why Sean was so upset. Sean's roommate is exhibiting symptoms of _____ disorder.
 - a. antisocial personality
 - b. manic
 - c. dissociative identity
 - d. conduct
19. Lucas's father has been diagnosed with alcoholism. Which of the following statements about Lucas would be most accurate?
 - a. Lucas has no more chance of developing an alcohol problem than does anyone else.
 - b. Lucas will probably also develop alcoholism.
 - c. Lucas might be less sensitive than other males to the effects of alcohol.
 - d. If Lucas is Jewish, he will be more susceptible to alcoholism.

20. Aaron is an infant who shows no signs of attachment to his parents. He doesn't like to be held and doesn't smile or laugh. Of the following, Aaron is most likely experiencing _____ disorder.
- infantile schizotypal
 - autistic
 - antisocial personality
 - narcissistic personality

Total Correct (See answer key) _____

Sample Quiz 2

Use this quiz to reassess your learning after taking Quiz 1 and reviewing the chapter.

- According to the infrequency criterion, behavior would be considered abnormal if it
 - caused discomfort.
 - was uncommon.
 - was bizarre but situationally appropriate.
 - impaired a person's ability to function.
- Stephen, a college student, drinks so much every weekend that he is barely able to function on Monday. Stephen's behavior would be labeled abnormal by the _____ approach.
 - neurobiological
 - practical
 - diathesis-stress
 - logical
- A woman disappeared during the Bosnian war, and two years later she showed up at home, with no memory for the time she was away. It was later discovered that she had created a whole new identity, living and working in another town under a different name. This woman may have suffered from
 - dissociative amnesia.
 - dissociative fugue.
 - dissociative identity disorder.
 - conversion disorder.
- Michael is reacting poorly to the news that his closest friend is dead. He is experiencing insomnia and sometimes believes he hears his friend's voice. After his condition worsens, Michael is diagnosed with schizophrenia. Ellyn maintains that Michael is having difficulties in coping because he inherited a predisposition toward schizophrenia, but she says it never would have appeared if he hadn't lost his closest friend. Ellyn is explaining Michael's abnormal behavior using the _____ model.
 - diathesis-stress
 - social-cognitive
 - sociocultural
 - humanistic
- Mary Sue, a brilliant neurosurgeon, visits the local animal shelter every morning and lectures the animals on the dangers of ingesting poisonous microbes. Although her behavior is considered a bit strange, the shelter's workers like having someone lavish attention on the animals. Afterward, Mary Sue goes to work and starts her day on time. Mary Sue's behavior would be considered abnormal according to which approach or criterion?
 - Statistical infrequency
 - Psychopathological
 - Logical
 - Practical
- Which of the following is *not* a problem with our present diagnostic system for psychological disorders?
 - People's problems often do not fit neatly into a single category.
 - The same symptoms may appear as part of more than one disorder.
 - Interrater reliability is not very strong, except for personality disorder.
 - Diagnoses are judgments, and personal biases may play a part.

7. Because Shantha has recurring thoughts about losing her belongings, she is continually checking the location of knickknacks and making sure her doors are locked. Shantha's strange behavior is most likely
 - a. an obsession.
 - b. a compulsion.
 - c. due to mania.
 - d. due to a conversion disorder.
8. Frank is so afraid of getting sick at the dinner table and being humiliated that he will not eat at a restaurant. Frank has
 - a. a specific phobia.
 - b. agoraphobia.
 - c. a social phobia.
 - d. an obsessive-compulsive disorder.
9. Dr. Arenas, who has a psychodynamic orientation, is seeing a client with a conversion disorder. What will Dr. Arenas most likely say is the explanation for the patient's conversion disorder?
 - a. The client has been reinforced for showing fear.
 - b. The client's unconscious conflicts produced anxiety, which showed itself as a physical symptom.
 - c. The client's repressed memories may have caused the amnesia.
 - d. The client views the world as an unfriendly place.
10. Hans, a police officer, was working the night shift when he came upon a young man who claimed that he could not remember his name, where he lived or worked, or anything else about himself. Most likely the mystery person displays
 - a. dissociative disorder.
 - b. antisocial personality disorder.
 - c. dissociative identity disorder.
 - d. schizophrenia.
11. Social-cognitive theorists would probably say that people who _____ are most likely to become depressed.
 - a. exaggerate the dark side of events
 - b. blame themselves when things go wrong
 - c. jump to overly pessimistic generalizations
 - d. All of the above
12. Philip displays bipolar I disorder. Which statement would best describe him?
 - a. He is sometimes very depressed and sometimes in a pleasant mood.
 - b. He is alternately severely depressed and wildly elated.
 - c. He has sudden onsets of depression that last for a few hours and then he feels fine.
 - d. His disorder is a very common one.
13. Mercedes has just brought home a dog from the pound. She was told that the dog's previous owners kept it on a leash and beat it daily for no reason. Mercedes notices that when the neighborhood kids bother the dog, it does not even try to run away. Mercedes' dog most likely has
 - a. generalized anxiety.
 - b. learned helplessness.
 - c. hypersensitive brainstem mechanisms.
 - d. enlarged ventricles.
14. Which of the following is an obsession?
 - a. Hearing voices in your head telling you to bang your head against a wall
 - b. Believing that you are the center of the universe
 - c. Constantly worrying about coming into contact with germs
 - d. Constantly checking your car to make sure the tires aren't flat
15. Childhood externalizing behavior problems include
 - a. problems that create distress within the child.
 - b. autistic disorder.

- c. attention-deficit hyperactivity disorder.
 - d. all of the above.
16. Schizophrenia means
- a. split emotions, alternating between very positive and very negative moods.
 - b. split personality, the fracturing of one identity into multiple personalities.
 - c. split identity, never being sure that who you think you are is who you really are.
 - d. split mind, the separating of normally integrated mental processes.
17. What type of personality disorder would you expect to find among people in jail for fraud?
- a. Narcissistic
 - b. Depressive
 - c. Antisocial
 - d. Mood
18. Which of the following is *not* suggested by the vulnerability model of schizophrenia?
- a. Vulnerability to schizophrenia is mainly biological.
 - b. Cold, unresponsive parenting leads to a regression to childhood, which causes schizophrenia.
 - c. Vulnerability is influenced partly by abnormalities associated with prenatal and birth complications.
 - d. Inadequate coping skills may play a role in determining whether schizophrenia actually appears in a person.
19. Victor, a ten-year-old, tells a psychologist that he first came to the court system after setting a car on fire at age eight. In the numerous police contacts since then, he has been accused of theft, assault, and willful destruction of property. Victor most likely has _____ disorder.
- a. autistic
 - b. narcissistic personality
 - c. conduct
 - d. schizotypal personality

20. Willis is accused of killing his parents, but he doesn't seem to understand what is going on. He continues to ask to see his parents and wants to go home with them. Willis may be declared mentally incompetent to stand trial if he
- a. does not understand the charges even after treatment with psychoactive drugs.
 - b. shows he had an irresistible impulse to murder his parents.
 - c. did not know that killing his parents would be permanent.
 - d. is diagnosed with a major psychological disorder.

Total Correct (See answer key) _____

ANSWERS TO MULTIPLE-CHOICE QUESTIONS

Circle the question numbers you answered correctly.

Sample Quiz 1

1. *d* is the answer. The impaired functioning criterion, part of the practical approach, asks whether a person can display the behavior in question and still meet the demands of everyday life. (see Defining Psychological Disorders)
 - a. *c*. The impaired functioning criterion is not part of the statistical infrequency or norm violation criteria.
 - b. Psychopathology, another word for mental illness, is not an approach to defining abnormality.
2. *d* is the answer. To conform, one follows the practices of the majority. Statistically, behaviors that are displayed by the majority of people are normal. According to the norm violation criterion, society determines which social rules to follow. Both criteria are problematic because some of the world's unique (nonconforming) people might thus be considered abnormal. (see Defining Psychological Disorders)
 - a. According to the practical approach, normal behavior can be unique (not seen frequently in other people) as long as the demands of everyday life are met and the behavior is situationally appropriate (approved of by others in that situation).
 - b. *c* is also correct.
 - c. *b* is also correct.

3.

a is the answer. According to the humanistic model, failure to be in touch with and express one's true feelings causes an obstruction in the self-actualization process. When this happens, the person distorts his or her perceptions of reality, which causes behavior disorders. (see Explaining Psychological Disorders)

b. According to the neurobiological model, problems in anatomy and physiology cause abnormal behavior.

c. Psychopathology is another word for mental illness, not an approach to defining abnormal behavior.

d. A person's perception of reality is a cause of abnormal behavior, according to the humanistic model, but perception is not a synonym for the name of this model.
4.

c is the answer. The diathesis-stress model proposes that genetic predispositions for abnormal behavior are not necessarily expressed, unless environmental stressors elicit them. (see Explaining Psychological Disorders)

a. The sociocultural model suggests that social factors alone can cause abnormal behavior.

b. The neurobiological model argues that abnormal behavior is caused by physical problems.

d. The humanistic model emphasizes unique perceptions of reality, and failure to be in touch with one's true feelings can cause abnormal behavior.
5.

d is the answer. (see Classifying Psychological Disorders)

a, b, c. The five axes comprise major disorder description, mental retardation or personality disorders, physical condition, stress level, and highest functioning level.
6.

a is the answer. Kat becomes anxious when she thinks about leaving her home. This is a symptom of agoraphobia. (see Anxiety Disorders)

b. Being unable to attend class is a consequence of Kat's fear of leaving her apartment, but it is not the object of her phobia.

c. Panic attacks are characterized by extreme terror, racing heartbeat, and, sometimes, the feeling of going crazy. Kat did not experience any of these symptoms.

d. There is no mention of tests or test anxiety in the question. Kat is afraid of leaving her apartment.
7.

c is the answer. Social-cognitive theorists see compulsive behaviors as learned habits that allow a person to escape or avoid anxiety-provoking situations. For Heidi, who is painfully shy, new social situations cause extreme anxiety. (see Anxiety Disorders)

a. A psychodynamic therapist would look for unconscious conflicts. Laurence is focusing on the behavioral basis of Heidi's problem.

b. A humanistic therapist might suggest that Heidi's behavior is caused by her unique perceptions of social situations.

d. Those who view abnormal behaviors as symptoms of neurobiological or medical problems would look for physiological irregularities.
8.

d is the answer. Axis V evaluates the highest level of adaptive functioning over the previous year. This is not mentioned in Sergio's report. (see Classifying Psychological Disorders)

a. Axis I lists descriptions of the major psychological disorders. Sergio's patient is experiencing major depressive disorder.

b. Axis II lists mental retardation and personality disorders. Sergio's patient has a dependent personality.

c. Axis IV rates the level of stress experienced in the recent past. Sergio's patient has experienced very minor stress in the past few months.

9. *a* is the answer. (see Anxiety Disorders)
 - b.* A social phobia is the fear of doing something that would cause embarrassment in public.
 - c.* Agoraphobia is the fear of leaving home or being away from a loved one.
 - d.* Panic disorder causes moments of terror in which the person believes he or she will die.
10. *a* is the answer. Typical conversion disorders involve functional impairment, such as blindness, paralysis, or deafness, with no apparent physical cause. (see Somatoform Disorders)
 - b.* Pain disorder is characterized by severe pain with no apparent cause.
 - c.* Hypochondriasis is characterized by constant fear of becoming seriously ill.
 - d.* People with somatization disorder or hypochondriasis have a tendency to complain of vague symptoms.
11. *a* is the answer. Severe pain in the chest, neck, or back with no apparent physical cause is a classic symptom of the somatoform disorder called pain disorder. (see Somatoform Disorders)
 - b.* A person with hypochondriasis worries about being stricken with a serious disease and often reports vague symptoms. Severe pain is not a vague symptom.
 - c.* A person with paranoia usually worries about being persecuted by a particular person or group.
 - d.* Somatization disorder involves vague reports of unrelated problems, but Tomas was quite specific about his chest pain.
12. *c* is the answer. Dissociative disorders involve some degree of disruption in memory, consciousness, or personal identity. According to the psychodynamic model, psychological disorders are caused by unresolved unconscious psychological conflicts. When they threaten to become conscious and cause anxiety, the individual finds a way to keep them in the unconscious. To accomplish this, some people may forget not only unconscious material but also who they are or any of the personal bits of information that identify them. (see Dissociative Disorders)
 - a.* A social-cognitive theorist would say that an individual has been rewarded in some way for dissociating. Perhaps distressing anxiety is removed when the person forgets her or his identity or escapes into another personality.
 - b.* A humanistic theorist would say that an individual's multiple personalities actually represent the overt expression of dramatically conflicting perceptions of the world.
 - d.* A sociocultural theorist would look to society, the environment, and social roles for the cause of a disorder.
13. *b* is the answer. Paul has not only forgotten about his previous life, but he has moved to a new location and assumed a new identity as a student named Nuwanda. (see Dissociative Disorders)
 - a.* ~~Dissociative amnesia is forgetting personally relevant information, but one does not move to a new location and create a new identity.~~
 - c.* Conversion disorders are a type of somatoform disorder in which people experience physical symptoms, like paralysis, that do not have a physical cause.
 - d.* Schizophrenia is characterized by more disordered thoughts and perceptions.
14. *b* is the answer. Weight loss or gain and sleep changes, including oversleeping or insomnia, are typical of depression. (see Mood Disorders)
 - a. d.* Weight loss or gain and sleeping problems do not usually occur in obsessive-compulsive disorder or hypochondriasis.
 - c.* There is no disorder known as hyperchondriasis.
15. *b* is the answer. Cyclothymic disorder is a less severe version of bipolar I disorder. Since Enya is still able to work, her swings are not as extreme as the swing from mania to depression. (see Mood Disorders)

- a.* Enya cycles between happiness and sadness; she is not just sad. In addition, major depressive disorder is more debilitating than what Enya is experiencing. People with major depressive disorder feel hopeless and worthless for weeks or months and lose interest in recreation, friends, and work.
 - c.* Dysthymic disorder is a less severe form of depression in which people feel the sadness and lack of pleasure associated with depression, but less intensely and for a longer time.
 - d.* Mania is an agitated, ecstatic, energetic state. Enya cycles between happiness and sadness.
16. *c* is the answer. Negative symptoms are the absence of normal mental processes, in this case, emotional responses. (see Schizophrenia)
- a.* Delusions are positive symptoms, undesirable additions to one's mental life.
 - b.* The adoption of another personality is a symptom of dissociative identity disorder.
 - d.* Hallucinations are positive symptoms, undesirable additions to one's mental life.
17. *a* is the answer. Juan is having persistent, unfounded beliefs that people around him are capable of reading his thoughts. (see Schizophrenia)
- b.* Hallucinations are false perceptions. Juan is not hearing or seeing in the absence of sensations.
 - c.* Obsessions are persistent, unwanted ideas that cannot be dispelled by reasoning. Juan is being governed by his unfounded beliefs, not by unwanted ideas.
 - d.* Loose associations are the tendencies for thoughts to fail to follow a logical sequence even though they occur in the same context.
18. *a* is the answer. Sean's roommate displays symptoms of antisocial personality disorder through his cold, unthinking, and unscrupulous behaviors. (see Personality Disorders)
- b.* There is no such thing as manic disorder. Mania is a very agitated, usually elated, emotional state that is one part of bipolar I disorder.
 - c.* Dissociative identity disorder is characterized by the display of more than one personality. Sean's roommate does not fit this description.
 - d.* Conduct disorder is a childhood disorder typified by aggressive, disobedient, and destructive behaviors.
19. *c* is the answer. Sons of people with alcoholism do tend to be less sensitive than other males to the effects of alcohol, a factor that may contribute to greater consumption. It is unclear whether this reduced sensitivity reflects a biological predisposition. (see A Sampling of Other Psychological Disorders)
- a.* Heredity does appear to play a role in alcohol abuse, especially among men. However, the exact role of genes or the strength of their influence is still unclear.
 - b.* The genetic component of alcoholism may not be as strong as once believed, so this statement is not accurate.
 - d.* As a group, Jews have a lower rate of alcoholism than is found in other groups, perhaps because all but moderate drinking tends to be discouraged in their culture.

20. *b* is the answer. Autistic disorder is a type of childhood disorder. Children with autistic disorder are not attached to caregivers, do not make eye contact, and are generally unable to be social. They may rock themselves and play with objects endlessly. (see A Sampling of Other Psychological Disorders)
- a.* There is no such thing as infantile schizotypal disorder.
 - c.* Antisocial personality disorder is a long-term pattern of irresponsible, rash, unprincipled behavior.
 - d.* Narcissistic personality disorder is characterized by an exaggerated sense of self-importance and a need for attention.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 1 that you answered correctly.

Sample Quiz 2

1. *b* is the answer. The statistical infrequency criterion says that a behavior is normal if many people in a given population display it, and abnormal if few people display the behavior. (see Defining Psychological Disorders)
 - a.* The practical approach considers the discomfort that a particular behavior causes as a factor for defining abnormality.
 - c.* Content and appropriateness are evaluated by the practical approach to defining abnormality.
 - d.* Meeting the demands of everyday life is part of the impaired functioning criterion, an important feature of the practical approach.
2. *b* is the answer. Stephen's behavior prevents him from meeting the demands of his everyday life. Therefore, his behavior meets the impaired functioning criterion in the practical approach. (see Defining Psychological Disorders)
 - a.* The neurobiological model is an explanation of abnormal behavior that emphasizes problems in anatomy and physiology.
 - c.* The diathesis-stress model is also used to explain behavior. It proposes that people with disorders may have had a genetic predisposition to develop the disorder, but that environmental stressors brought it on. The item doesn't say that Stephen has an inherited tendency toward alcoholism or another disorder.
 - d.* There is no such thing as the logical approach to defining abnormality.
3. *b* is the answer. Fugue is characterized by sudden loss of personal memory and the adoption of a new identity in a new locale. (see Dissociative Disorders)
 - a.* Dissociative amnesia involves sudden memory loss, but the person does not leave home or create a new identity.
 - c.* Dissociative identity disorder is characterized by seeming existence of more than one personality in a single individual.
 - d.* Conversion disorder is a somatoform condition in which people are dissociated from a part of their body.

4. *a* is the answer. The diathesis-stress model suggests that some people inherit a tendency toward a disorder, but that it may not develop unless environmental stressors are severe. (see Explaining Psychological Disorders)
 - b*. The social-cognitive approach emphasizes learning.
 - c*. The neurobiological model explains psychological problems as due to problems in anatomy and physiology..
 - d*. Humanistic theorists emphasize perceptions.
5. *a* is the answer. According to the statistical infrequency criterion, behaviors are abnormal unless displayed by a large number of people. Few, if any, neurosurgeons lecture animals on the dangers of ingesting dangerous microbes. (see Defining Psychological Disorders)
 - b*. There is no such thing as the psychopathological approach to defining abnormality.
 - c*. There is no such thing as the logical approach to defining abnormal behavior.
 - d*. The practical approach evaluates behavior content in the context of a situation. Mary Sue's behavior is not harmful and does not interfere with her everyday functioning, although it is a bit bizarre. However, this approach states that if everyone in the situation approves, even a bizarre behavior may not be considered abnormal. The shelter's workers like to see Mary giving the animals attention every day. Her behavior is not abnormal in this context.
6. *c* is the answer. Since the adoption of DSM-IV, interrater reliability has *improved*, except for personality disorders and other complex conditions. (see Classifying Psychological Disorders)
 - a*, *b*, *d*. These are all problems with DSM-IV, the present diagnostic system.
7. *b* is the answer. Compulsions are behaviors that the person thinks will keep harm from coming to him or herself, family, or friends. (see Anxiety Disorders)
 - a*. An obsession is an unwanted, persistent thought.
 - c*, *d*. Mania and conversion disorder do not cause unwanted, persistent thoughts and repetitive behaviors.
8. *c* is the answer. Never displaying a behavior in public, such as eating or writing, for fear of humiliation is called a social phobia. Frank is afraid that he will embarrass himself by getting sick in public, so he refuses to eat at restaurants. (see Anxiety Disorders)
 - a*. Specific phobias include fear of objects or situations, such as heights, dogs, or air travel, but do not include any social factors. In other words, people may have a fear of spiders and not feel worried that their fear will humiliate them.
 - b*. Agoraphobia is a fear of leaving one's home and, sometimes, of being alone.
 - d*. Obsessive-compulsive disorder is characterized by taking great pains to be organized, neat, clean, or particular about details or by recurring, unpleasant thoughts.
9. *b* is the answer. Conversion disorders are physical symptoms, like paralysis or blindness, without physical causes. A psychodynamic theorist would be likely to say that a person is translating an unacceptable unconscious desire or conflict into a symptom that excuses the person from the difficult situation. (see Somatoform Disorders)
 - a*. The client may have been reinforced by getting out of an activity due to physical disability, but not for showing fear.
 - c*. Repressed memories are a psychodynamic concept, but amnesia is not part of conversion disorder.
 - d*. A humanistic explanation would deal with such perceptions.

10. *a* is the answer. A dissociative disorder is characterized by disruptions in memory, consciousness, or identity. (see Dissociative Disorders)
 - b.* Someone with antisocial personality disorder usually displays a pattern of impulsive, selfish, and even criminal behavior. However, the symptoms associated with personality disorders do not usually include memory loss.
 - c.* Symptoms of dissociative identity disorder may include blackouts or a loss of memory over a certain period of time when an alternate personality takes over, but do not include a loss of personal information, such as one's name.
 - d.* A person with schizophrenia experiencing thought blocking or withdrawal may feel as though he or she is being prevented from remembering his or her own name, job, or family, but there are no specific symptoms of memory loss typical of schizophrenia.
11. *d* is the answer. A social-cognitive theorist would say that our thinking, positive or negative, or our blaming ourselves instead of the environment can lead to depression. (see Mood Disorders)
12. *b* is the answer. Bipolar I disorder involves extreme changes in mood and, consequently, behavior. (see Mood Disorders)
 - a, c.* A pleasant mood is normal, so there is only one symptom present in each answer: depression. Both mania and depression must be present before a bipolar disorder is suspected.
 - d.* Bipolar disorders are very rare.
13. *b* is the answer. Mercedes's dog has learned helplessness: it has learned or come to believe that its actions—barking and growling—will not control its environment by scaring the children away. (see Mood Disorders)
 - a.* Generalized anxiety is worry and fear detached from any specific cause.
 - c.* Hypersensitive brainstem mechanisms are associated with panic disorder in humans.
 - d.* Enlarged ventricles are associated with schizophrenia in humans.
14. *c* is the answer. An obsession is an upsetting, persistent, unwanted thought that cannot be reasoned away. (see Anxiety Disorders)
 - a.* Hearing voices is a hallucination.
 - b.* A false belief is a delusion.
 - d.* A repetitive behavior, like constant checking, is a compulsion.
15. *c* is the answer. (see A Sampling of Other Psychological Disorders)
 - a.* Internalizing disorders, such as separation anxiety disorder, cause internal distress.
 - b.* Autistic disorder fits neither the internalizing nor the externalizing categories.
 - d.* only *c* is the answer.
16. *d* is the answer. "Split mind" refers to the peculiarities of schizophrenic thinking that are a split from normal reality-based, integrated thinking. (see Schizophrenia)
 - a.* This option actually describes bipolar I disorder.
 - b.* Split personality defines dissociative identity disorder.
 - c.* Split identity describes a dissociative disorder in which one's hold on one's identity is disrupted.

17. *c* is the answer. People with antisocial personality disorder display a long-term, persistent pattern of impulsive, selfish, unscrupulous, and even criminal behavior. (see Personality Disorders)
 - a.* The main characteristic of narcissistic personality disorder is an exaggerated sense of self-importance. Although these people may be annoying in their constant quest for attention from the right people, they usually are not free of guilt, nor do they tend to commit crimes.
 - b.* Depression is a mood disorder, not a personality disorder, involving feelings of sadness and hopelessness and a loss of self-worth.
 - d.* A mood disorder is not a personality disorder. Mood disorders, such as depression or mania, involve changes in emotions.
18. *b* is the answer. Poor parenting and regression to childhood are psychological theories for schizophrenia that have not received strong research support. Psychological factors alone are no longer considered to be the primary causes of schizophrenia. (see Schizophrenia)
 - a, c, d.* These are all part of the integrative view of the vulnerability model.
19. *c* is the answer. Conduct disorder falls under the externalizing category. Its primary features are aggressive, destructive, disobedient behaviors. (see A Sampling of Other Psychological Disorders)
 - a.* Autistic disorder is neither an externalizing nor internalizing disorder. It is a severe condition usually diagnosed in the first 30 months of life and is characterized by ritualistic play, lack of attachment to caregivers, and lack of positive emotional expressions.
 - b.* Narcissistic personality disorder is not a disorder of childhood and is identified when a person is egotistical, overly sensitive to criticism, and in need of attention.
 - d.* Schizotypal personality disorder is similar to schizophrenia, but not as severe. People with this disorder may have odd beliefs, but they do not hallucinate.
20. *a* is the answer. Mentally incompetent to stand trial is a rare outcome, because therapy or psychoactive drugs can usually produce at least temporary competence. (see Mental Illness and the Law)
 - b.* The irresistible impulse test is related to judgments of not guilty by reason of insanity. Federal cases do not allow this lack-of-control criterion to be used to support a claim of insanity.
 - c.* If he didn't understand what he was doing, he may be not guilty by reason of insanity, but he may be competent to stand trial.
 - d.* Diagnosis with a psychological disorder may or may not be enough to show mental incompetence; after all, many people with disorders are able to understand court proceedings.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 2 that you answered correctly.

For each question you answered correctly, circle its number. (Quiz 1 numbers are not shaded; Quiz 2 numbers are shaded.) Are there patterns in the types of questions or the topics you got wrong that could direct your further study? Did you improve from Quiz 1 to Quiz 2?

CHAPTER 16

Treatment of Psychological Disorders**MULTIPLE-CHOICE QUESTIONS****Sample Quiz 1**

1. The common features of any type of therapy include
 - a. a client or patient.
 - b. someone socially accepted as being able to help the client.
 - c. a theoretical approach to understanding and treating the client's problems.
 - d. All of the above
2. Sayumi is a licensed psychologist. Which of the following statements is most likely true of her? Sayumi has a(n)
 - a. doctoral degree in clinical psychology.
 - b. psychodynamic approach to therapy.
 - c. private practice.
 - d. M.D. degree.
3. The focus of Freudian psychoanalysis is on
 - a. getting the client in touch with his or her present feelings.
 - b. helping the client gain insight into unconscious problems.
 - c. replacing problematic behaviors with desirable behaviors.
 - d. teaching the client new ways of thinking.
4. Carl Rogers developed _____ therapy.
 - a. client-centered
 - b. rational-emotive
 - c. cognitive-behavior
 - d. object relations
5. Interpersonal therapy, individual analysis, object relations, supportive-expressive therapy, and ego analysis are all variations of
 - a. client-centered therapy.
 - b. psychoanalysis.
 - c. cognitive restructuring.
 - d. behavior modification.

6. As Dwayne prepares for an exam, he comments to his friend, Rerun, "This test is gonna be a seize." Rerun says, "A seize? Don't you mean 'a breeze?'" A _____ therapist would be most likely to think that Dwayne's comment indicates that he unknowingly fears freezing up during the exam and can't admit to it consciously.
- behavioral
 - community
 - humanistic
 - psychodynamic
7. Vivian is tearfully telling a friend that she is depressed and does not even know why. Her friend says, "You seem to be so unhappy, a little confused, and maybe a bit scared, too." Vivian's friend is using which method associated with client-centered therapy?
- Sympathy
 - External frame of reference
 - Reflection
 - Modeling
8. Pat is afraid of using a computer. To counteract Pat's misconceptions about what could happen if she used a computer, her therapist suggests a dialogue exercise. Pat is to imagine that she is talking to a computer and fill in what the computer would "say" to her. Pat's therapist is using _____ therapy.
- client-centered
 - Gestalt
 - psychoanalysis
 - systematic desensitization
9. A _____ therapist would use rational-emotive behavior therapy.
- psychoanalytic
 - humanistic
 - cognitive-behavior
 - biological
10. In behavioral therapy, associating an unpleasant stimulus with the simultaneous occurrence of an undesirable behavior is called
- aversive conditioning.
 - object relations therapy.
 - flooding.
 - building an anxiety hierarchy.
11. Harvey is a psychotherapist. In treating his clients, he uses systematic desensitization and participant modeling in cases of phobia. What type of therapist is Harvey?
- Behavioral
 - Psychoanalytic
 - Humanistic
 - Biological
12. Bonnie fears driving in the mountains. Her therapist has suggested that they take a ride into the mountains for several hours. What method is the therapist proposing?
- Aversive conditioning
 - Modeling
 - Punishment
 - Flooding
13. As part of Karla's therapy session, she spends an evening role-playing with other members of her group. Situations such as returning faulty merchandise, sending improperly prepared food back to the cook in a restaurant, and telling her roommate when she needs quiet in the room are the topics of the evening. Karla is experiencing
- depression.
 - punishment.

- c. assertiveness training.
 - d. aversive conditioning.
14. Group therapy is associated with which theoretical approach?
- a. Group therapy has no particular theoretical approach.
 - b. Humanistic
 - c. Behavioral
 - d. Psychoanalytical
15. When Shau-Jin is angry at Wendy, he often says things like, "Why do you always criticize me?" and, "You're such a nag!" The therapy that would focus most on their communication pattern would be
- a. couples therapy.
 - b. extinction.
 - c. rational-emotive behavior therapy (REBT).
 - d. psychoanalysis.
16. According to the Ethical Standards of the American Psychological Association, a therapist may disclose information mentioned by a client during therapy when
- a. the client is applying for a job and the employer asks for information.
 - b. the client ends therapy.
 - c. defending herself or himself against a malpractice charge.
 - d. Any of the above
17. In the past, broken bones, memory loss, speech disorders, and even death were associated with which type of treatment?
- a. Family therapy
 - b. Lithium
 - c. Electroconvulsive therapy
 - d. Punishment
18. Tico is talking incoherently and is experiencing so many hallucinations and delusions that her psychiatrist will most likely prescribe a(n)
- a. antidepressant.
 - b. anxiolytic.
 - c. depressant.
 - d. neuroleptic.
19. Which of the following is *not* a criticism of drug therapy?
- a. Drug therapy may treat only symptoms, not the problem itself.
 - b. Drug therapy may make patients depend on the drug, instead of on their own efforts, for improvement.
 - c. Many drugs have unwanted side effects.
 - d. Drug therapy is more expensive than any other kind of therapy.
20. Liesette tries to influence lawmakers to provide more help for people in poverty because she believes such a tactic will prevent psychological problems caused by malnutrition, overcrowding, and homelessness. Liesette most likely is a _____ psychologist.
- a. behavior
 - b. community
 - c. humanistic
 - d. psychodynamic
- Total Correct (See answer key) _____

Sample Quiz 2

Use this quiz to reassess your learning after taking Quiz 1 and reviewing the chapter.

1. The type of therapy to be used should be based on knowledge of
- a. the approach and methods the client is comfortable with.
 - b. a potential therapist's track record.

- c. the potential for a positive client-therapist relationship.
 - d. All of the above
2. Simone asks her clients to remember their childhood experiences in order to gain insight into unconscious processes and thoughts. Simone is probably a _____ therapist.
- a. behavioral
 - b. Gestalt
 - c. client-centered
 - d. psychodynamic
3. Which of the following would a psychoanalyst be *least* likely to use in therapy?
- a. Dream interpretation
 - b. Ego analysis
 - c. Free association
 - d. Modeling
4. Empathy in client-centered therapy is
- a. perceiving a client's view of reality.
 - b. restating or paraphrasing a client's words.
 - c. unconditional positive regard.
 - d. congruence between a therapist's words and actions.
5. Which of the following describes flooding?
- a. A client is gradually exposed to a feared stimulus.
 - b. A client is placed in a harmless but fearful situation and not allowed to escape.
 - c. A client learns not to let negative thoughts overwhelm or flood the mind.
 - d. A client receives a negative stimulus following an undesirable behavior.
6. Mac is a therapist who relies on his clients' natural drive toward growth. Marcia tells him that she thinks she's so ugly it is not worth it to exercise or try to dress nicely, and she asks him if he thinks she is ugly. Rather than interpreting Marcia's behavior, Mac discloses his honest reaction, saying, "Right now you think it is futile to try to improve your looks. Although I think you are attractive, what *you* think is much more important and it seems you are discouraged." Mac is exhibiting _____, which is associated with _____ therapy.
- a. analysis of transference: psychodynamic
 - b. congruence: client-centered
 - c. reflection: cognitive-behavioral
 - d. sympathy: humanistic
7. In psychoanalysis, transference occurs when
- a. unconscious thoughts become conscious.
 - b. a client transfers feelings about a significant person onto a therapist.
 - c. the manifest content of a dream is translated into latent content.
 - d. free association reveals unconscious conflicts.
8. Aversive conditioning is
- a. based on operant conditioning.
 - b. based on classical conditioning.
 - c. used to increase a behavior's occurrence.
 - d. based on reward and punishment.
9. Li is frightened to leave his apartment. His therapist has instructed him to make a list of progressively frightening thoughts about leaving home. Alec is constructing a(n) _____ as part of _____.
- a. anxiety hierarchy: systematic desensitization
 - b. fear manifest: cognitive restructuring
 - c. anxiety hierarchy: flooding
 - d. fear manifest: psychoanalysis

10. Amy has been sent to a camp for children with behavior disorders. On her first day, she and her counselor decide what behaviors Amy will learn to do on a daily basis. These include playing cooperatively, speaking respectfully to the counselors, and helping clean the dining hall after dinner. Immediately following the successful display of a behavior, Amy receives a pink piece of cardboard. Each day she can trade these pieces of cardboard for special activities and privileges. This is an example of
 - a. aversive conditioning.
 - b. flooding.
 - c. a token economy.
 - d. cognitive restructuring.
11. Virtual reality has been successfully used to treat
 - a. schizophrenia.
 - b. conduct disorder.
 - c. posttraumatic stress disorder.
 - d. phobia.
12. Chung Wa has gone to see a therapist because she is very depressed and dislikes herself. She doesn't get perfect grades and is not the most popular person on her dorm floor. What kind of therapy do you think would be best for Chung Wa?
 - a. Antidepressant drugs
 - b. Rational-emotive behavior therapy
 - c. Aversive conditioning
 - d. Token economy
13. Roberto has a dog phobia. He and his therapist go for a walk, and Roberto watches from across the street as his therapist approaches people who are walking their dogs. The therapist asks the owner if the dog is friendly, lets the dog sniff his hand, and gently pats the dog. The therapist is using _____ to help Roberto.
 - a. token economies
 - b. modeling
 - c. flooding
 - d. classical conditioning
14. Alex is a young boy whose parents recently divorced. His parents want him to see that many children are making the adjustment he's making; therefore, his parents would most likely seek _____ for Alex.
 - a. Gestalt therapy
 - b. group therapy
 - c. psychoanalysis
 - d. social skills training
15. In which of the following scenarios may a therapist *not* reveal confidential information?
 - a. When discussing a case with a family member
 - b. When defending herself or himself against a malpractice charge
 - c. When a client requires hospitalization
 - d. When a therapist feels a client may physically harm another person
16. Jill's therapist has recommended electroconvulsive therapy (ECT). Jill is probably experiencing
 - a. schizophrenia.
 - b. depression.
 - c. hallucinations.
 - d. anxiety.
17. Treatments whose effects have been validated by controlled experimental research are known as
 - a. meta-analyses.
 - b. psychoanalysis.
 - c. empirically-supported therapies.
 - d. client-centered.

18. Nina has been experiencing moods of extreme elation alternating with severe depression. What kind of drug will her doctor most likely prescribe?
- Tricyclics
 - Phenothiazines
 - Monoamine oxidase inhibitors
 - Lithium
19. When Terence takes fluoxetine (Prozac), serotonin remains in the synapse rather than flowing back into the presynaptic terminal. The antidepressant is
- acting as a receptor antagonist.
 - blocking reuptake.
 - causing tardive dyskinesia.
 - preventing anxiolytic action.
20. Michel has spent the morning teaching preschool teachers the early signs of psychological problems, hoping that children can be helped before their problems become severe. What kind of psychologist is Michel?
- Biological
 - Rational-emotive
 - Community
 - None of the above

Total Correct (See answer key) _____

ANSWERS TO MULTIPLE-CHOICE QUESTIONS

Circle the question numbers you answered correctly.

Sample Quiz 1

- d* is the answer. Therapies all involve a client, a therapist who is socially accepted as being able to help the client, and a theoretical approach (psychoanalytic, humanistic, behavioral, biological) to understanding the client's problems and treating them. (see Basic Features of Treatment)
- a* is the answer. Psychologists generally have a doctoral degree in clinical or counseling psychology. (see Basic Features of Treatment)
 - A psychologist would not necessarily have a psychodynamic approach. Sayumi could have a humanistic, behavior, cognitive-behavior, or eclectic approach.
 - Many psychologists work in academic settings or in clinics or hospitals.
 - A psychiatrist is required to have an M.D. degree, but a psychologist is not.
- b* is the answer. The focus of psychoanalytic therapy is to reveal and work through unconscious conflicts. (see Psychodynamic Psychotherapy)
 - Humanistic therapies help clients get in touch with and express their present feelings.
 - Behavior therapies usually focus on replacing undesirable behaviors with new ones.

- d.* Cognitive-behavior therapies focus on teaching the client new and more constructive ways of thinking.
4. *a* is the answer. Carl Rogers developed the humanistic methods of client-centered therapy (or person-centered therapy). (see Humanistic Psychotherapy)
- b.* Albert Ellis developed rational-emotive therapy.
- c.* Rational-emotive therapy is a type of cognitive-behavior therapy.
- d.* Object relations therapy is a variation on psychoanalysis.
5. *b* is the answer. All of these are contemporary variants of classical psychoanalysis. (see Psychodynamic Psychotherapy)
- a, c, d.* Only *b* is the answer.
6. *d* is the answer. A psychodynamic therapist would be likely to find unconscious meaning in behaviors. (see Psychodynamic Psychotherapy)
- a.* A behavioral therapist would focus on learning of behaviors, not unconscious meanings.
- b.* A community psychologist works to prevent disorders.
- c.* Humanistic therapists are interested in a client's viewpoint, but would be unlikely to assume that Dwayne could not become aware of his fear.
7. *c* is the answer. Vivian's friend is reflecting or paraphrasing what she is saying, especially the feeling and meaning. (see Humanistic Psychotherapy)
- a.* Sympathy involves expressing concern for someone else, but it does not involve paraphrasing what they are saying.
- b.* This is not a method associated with client-centered therapy. In fact, in using empathy the humanistic therapist tries to replace an external frame of reference by understanding what the client might be thinking and feeling.
- d.* Modeling is a technique of imitating positive behaviors used in behavioral therapy.
8. *b* is the answer. Gestalt therapy, a form of humanistic therapy, uses more dramatic methods to help clients become more self-accepting. Clients might carry on imaginary conversations with people, parts of themselves, or objects. (see Humanistic Psychotherapy)
- a.* Client-centered therapy is a type of humanistic therapy, but it allows the client to direct the course of a session.
- c.* Psychoanalysis seeks to uncover unconscious conflicts by interpreting transference, free association, and dreams.
- d.* Systematic desensitization is a behavioral treatment for phobias; however, it involves visualizing progressively more frightening situations while remaining calm.
-
9. *c* is the answer. Rational-emotive behavior therapy is a cognitive-behavior therapy. Clients are taught to recognize damaging thoughts and to replace them with more positive and functional thoughts. (see Behavior Therapy)
- a.* Psychoanalysts focus on revealing a person's unconscious thoughts and conflicts.
- b.* Humanistic therapists focus on a person's feelings and drive toward growth.
- d.* Biological therapists use biological treatments either alone or in conjunction with other forms of therapy to cause changes in nervous system functioning.
10. *a* is the answer. Aversive conditioning is used to decrease a behavior's occurrence. An unpleasant stimulus is experienced every time an undesirable behavior is displayed. (see Behavior Therapy)
- b.* Object relations therapy is a type of psychoanalytic therapy.
- c.* Flooding is based on extinction. A client is exposed to the entire object, situation, or event that he or she fears. Since the client cannot escape, he or she has the chance to realize that the fear is unfounded.
- d.* An anxiety hierarchy is used in systematic desensitization.

11. *a* is the answer. Harvey is a behavioral therapist because he uses methods based on learning theory. (see Behavior Therapy)
 - b.* A psychoanalyst would be far more likely to use free association, dream analysis, and other methods aimed at revealing unconscious material.
 - c, d.* A humanistic or biological therapist would probably not use systematic desensitization.
12. *d* is the answer. To use the flooding method, a client is placed in a feared but harmless situation and not allowed to escape. The person soon realizes that he or she has nothing to fear. Exposing Bonnie to the situation she fears and not allowing her to escape may help her overcome her fear of driving in the mountains. (see Behavior Therapy)
 - a.* Aversive conditioning is also used to decrease behavior. However, a client experiences a negative stimulus when she or he engages in the undesirable behavior.
 - b.* Modeling involves teaching a client desirable behaviors by demonstrating those behaviors and showing the client how to behave more calmly in feared situations. However, the client is not actually in the feared situation.
 - c.* Punishment, a procedure used to decrease a behavior, involves presenting a negative stimulus following an undesirable behavior.
13. *c* is the answer. Karla is learning how to be assertive in social situations. Remember, being assertive is not the same thing as being aggressive. Karla can be assertive, get her food prepared the way she likes it, and not be aggressive. (see Behavior Therapy)
 - a.* Karla may be a little bit depressed that she cannot get what she wants in social situations. However, this depression is a symptom of not being assertive.
 - b, d.* Punishment and aversive conditioning are used to decrease undesirable behaviors. Karla is in therapy to learn new behaviors, not to decrease old, undesirable ones.
14. *a* is the answer. Group therapy has no particular theoretical assumptions underlying it. Instead, groups are organized around a specific type of problem (such as alcoholism) or client (such as teenagers). (see Group, Family, and Couples Therapy)
 - b, c, d.* Group therapies are not associated with a particular theoretical approach.
15. *a* is the answer. Therapists often recommend couples therapy if communication with a partner seems to be a major problem. In couples therapy, people practice more constructive ways of getting ideas across. Rather than calling Wendy names or overgeneralizing, for example, Shau-Jin probably would be encouraged to say something about how he feels in the present situation. (see Group, Family, and Couples Therapy)
 - b.* Extinction removes the reinforcers that usually follow a behavior. It is a behavior therapy that doesn't work on communication skills.
 - c.* Rational emotive behavior therapy would concentrate on irrational ideas, not communication.
 - d.* Psychoanalysis would focus on unconscious conflicts rather than on communication.
16. *c* is the answer. Confidentiality is a critical aspect of therapy that is seldom violated. However, if a client brings a malpractice suit against the therapist, the records of their sessions could be important evidence of the therapist's efforts to help. (see Evaluating Psychotherapy)
 - a.* Employers do not have a right to information about confidential therapy sessions.
 - b.* The end of therapy does not signal the end of the obligation to protect a client's right to privacy.
 - d.* Only *c* is correct.
17. *c* is the answer. In the past, ECT did have serious side effects. However, now it is much more precise and less hazardous. (see Biological Treatments)
 - a.* Family therapy does not cause such problems, although it might be used to halt or prevent physical abuse among family members that may cause them.
 - b.* Lithium treatment for the bipolar disorders can be problematic, but the side effects mentioned in this question are not associated with this therapy.

- d.* Punishment as used by ethical behavioral therapists would never have such results.
18. *d* is the answer. Neuroleptics or antipsychotics reduce the intensity of psychotic symptoms such as Tico's. (see Biological Treatments)
- a.* Antidepressants improve mood but do not influence psychotic symptoms.
- b.* Anxiolytics or tranquilizers reduce tension and anxiety.
- c.* As discussed in Chapter 9, a depressant is a psychoactive drug that slows the activity of the central nervous system.
19. *d* is the answer. Drugs are not necessarily the most expensive form of therapy. Freudian psychoanalytic therapy, because it can take several years, is very expensive. (see Biological Treatments)
- a, b, c.* These are all problems with drug therapy.
20. *b* is the answer. Prevention of problems such as psychological disorders is the focus of community psychologists. (see Community Psychology: From Treatment to Prevention)
- a.* Behavior psychologists focus on learning.
- c.* Humanistic psychologists focus on perceptions.
- d.* Psychodynamic psychologists focus on unconscious conflicts.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 1 that you answered correctly.

Sample Quiz 2

Circle the question numbers you answered correctly.

1. *d* is the answer. The client should be comfortable with the methods used, should know the therapist's track record, and should feel capable of developing a positive relationship with the therapist. (see Basic Features of Treatment)
2. *d* is the answer. Psychodynamic therapists (or psychoanalysts) believe that exploring childhood experiences and thereby gaining understanding of unconscious processes are the keys to resolving mental illness. (see Psychodynamic Psychotherapy)
- a.* Behavioral therapists may focus on past learning experiences, but they usually deal with current behaviors, not unconscious processes and thoughts.
- b.* Gestalt therapists concentrate on identifying the problematic ways in which people may be behaving so that they live according to the expectations of others, not according to their true selves. Therapists may focus on the incorrect thought patterns that clients possess and the ways in which they defend against self-exploration.
- c.* Client-centered therapists focus on creating a therapeutic environment in which clients can explore the reasons for their problems and get themselves back on the track toward fulfillment and self-actualization.
3. *d* is the answer. Modeling is a behavior modification technique. (see Psychodynamic Psychotherapy)
- a, c.* Dream interpretation and free association are part of classical psychoanalysis.
- b.* Ego analysis is a contemporary psychodynamic treatment.
4. *a* is the answer. A client-centered therapist must empathize, or perceive the world from the client's point of view. (see Humanistic Psychotherapy)
- b.* Restating or paraphrasing a client's feelings is a way of demonstrating empathy.
- c.* Unconditional positive regard is necessary to let a client know that a therapist cares about and accepts the client as a person.
- d.* Congruence is the match between a therapist's words and actions toward a client. The therapist must actually experience, not just act out, unconditional positive regard and empathy for the client.

5. *b* is the answer. A client is exposed to the feared situation, object, or event and is not allowed to escape. Since the person cannot escape, he or she can come to realize that there is nothing to fear. (see Behavior Therapy)
- a.* Gradual exposure to a feared stimulus takes place in systematic desensitization or participant modeling.
 - c.* Cognitive restructuring can teach a client to replace destructive thoughts with more effective or constructive ones.
 - d.* Presenting an unpleasant stimulus after an undesirable behavior is called punishment.
6. *b* is the answer. Congruence between thoughts and actions is part of client-centered therapy. (see Humanistic Psychotherapy)
- a.* Analysis of transference is a psychodynamic technique in which the client's reaction to the therapist is compared to conflicts with significant others in childhood.
 - c.* Reflection is a client-centered therapy technique.
 - d.* You may have been thinking of empathy, which is a client-centered technique.
7. *b* is the answer. Psychoanalysts believe that if they reveal nothing about themselves, clients will begin to transfer onto them many feelings and attitudes about conflicts experienced with significant people in their lives. (see Psychodynamic Psychotherapy)
- a, d.* Free association does help reveal unconscious conflicts, making them conscious, but this process is not called transference.
 - c.* Interpreting a dream's manifest content in order to understand its symbolic or latent content is part of psychoanalytic treatment. This process is not called transference.
8. *b* is the answer. Aversive conditioning is based on classical conditioning. (see Behavior Therapy)
- a, d.* Methods such as token economies and punishment are based on operant conditioning principles.
 - c.* Aversive conditioning is used to decrease the occurrence of a specific behavior.
9. *a* is the answer. An anxiety hierarchy is a list of fear-producing situations that is constructed for use in systematic desensitization. (see Behavior Therapy)
- b, d.* There is no such thing as a fear manifest. (You may have been thinking of manifest content, which is used in psychodynamic dream analysis.)
 - c.* Li has constructed an anxiety hierarchy, but this hierarchy is a part of systematic desensitization, not flooding. Flooding is a behavioral technique in which a person is repeatedly put into the fear-producing situation until the conditioned fear response is extinguished.
10. *c* is the answer. The camp has set up a type of economic system in which campers receive tokens when they display behaviors they have agreed to work on. The campers can exchange their tokens for various forms of positive reinforcement. In Amy's case, her tokens are exchanged for special activities and privileges. Token economies serve to increase the occurrence of desirable behaviors. (see Behavior Therapy)
- a.* Aversive conditioning is used to decrease, not increase, a behavior's occurrence.
 - b.* Flooding is used to decrease a behavior, usually avoidance.
 - d.* Cognitive restructuring involves replacing negative and damaging thoughts with more constructive ones.
11. *d* is the answer. Used as part of systematic desensitization, virtual reality graded exposure has enabled clients to experience and work through vivid and intensely feared situations without actually being exposed to them. (see Behavior Therapy)
- a, b, c.* This technique has been used as part of treatments to help clients overcome specific unrealistic fears. Specific fears are not a primary component of these disorders.
12. *b* is the answer. Chung Wa's ideas about having everyone like her and being a perfect student are probably at the root of her depression. Rational-emotive therapy will help her recognize and eliminate these unhealthy thoughts. (see Behavior Therapy)

- a.* Chung Wa's depression might be alleviated by antidepressants, but it is obvious that her thought patterns about being liked and perfect will continue to cause her problems. Changing her thinking should alleviate her depression on a long-term basis.
 - c.* Aversive conditioning is used to decrease a specific behavior. Chung Wa needs to change her thought patterns, not a specific behavior.
 - d.* Token economies are used to increase the occurrence of desired behaviors. Chung Wa needs to change her thought patterns, not her overt behavior.
- 13. *b* is the answer. Modeling involves teaching a client desirable behaviors by demonstrating those behaviors and showing the client how to behave more calmly in feared situations. (see Behavior Therapy)
 - a.* Token economies involve receiving tokens for demonstrating desirable behaviors. The tokens can later be traded in for rewards or privileges. Roberto is not performing any behaviors; he is watching how his therapist behaves with dogs.
 - c.* Flooding involves placing a client in a feared but harmless situation. Once deprived of his or her normally rewarding escape pattern, the client has no reason for continued anxiety. If Roberto and his therapist had shut themselves in a small room with a gentle, friendly dog, this would have been the answer.
 - d.* Classical conditioning is a part of aversive conditioning and flooding. Modeling is based on operant conditioning.
- 14. *b* is the answer. Alex would meet other children of divorced parents in group therapy, which would make him feel less alone and allow him to learn from others. (see Group, Family, and Couples Therapy)
 - a.* Gestalt therapy could be used in a group format, but it would not require a group format.
 - c.* Psychoanalysis is an individual therapy.
 - d.* Social skills training is often done in groups, but would not focus on sharing concerns about parental divorce.
- 15. *a* is the answer. A therapist is bound by law to keep strictly confidential any information revealed by a client. He or she can discuss a case with a client's family only if the client gives permission. (see Evaluating Psychotherapy)
 - b, c, d.* These are all situations in which a therapist may release information given by a client.
- 16. *b* is the answer. ECT is currently used to treat depression that has not responded to other treatments. (see Biological Treatments)
 - a, c.* ECT was once used to treat schizophrenia, but isn't currently. Hallucinations are a symptom of schizophrenia and other serious psychopathologies.
 - d.* Drugs are used to treat anxiety.
- 17. *c* is the correct answer. Empirically-supported therapies have been experimentally validated for specific problems. (see Evaluating Psychotherapy)
 - a.* Meta-analysis is a research method that combines the results of many studies on the same topic.
 - b.* Psychoanalysis is a method of psychotherapy that seeks to help clients gain insight by recognizing and understanding unconscious thoughts and emotions.
 - d.* Client-centered is a humanistic therapeutic technique that allows the client to decide what to talk about, without direction, judgment, or interpretation from the therapist.
- 18. *d* is the answer. Lithium is used to treat bipolar disorders. (see Biological Treatments)
 - a, c.* Tricyclics and MAO inhibitors are used to treat depression.
 - b.* Phenothiazines are used to treat severe disorders such as schizophrenia.
- 19. *b* is the answer. Blocking reuptake keeps a neurotransmitter from returning to the presynaptic cell. (see Biological Treatments)
 - a.* A receptor antagonist does block neurotransmitters, but it blocks them from binding to a postsynaptic cell.

- c.* Tardive dyskinesia is a side effect caused by neuroleptics after years of use.
 - d.* Anxiolytics are anti-anxiety drugs.
20. *c* is the answer. Community psychologists seek both to treat and to prevent psychological problems. Michel believes that if psychological problems are detected in their early stages, treatment will be shorter, less expensive, and possibly more effective. (see Community Psychology: From Treatment to Prevention)
- a, b, d.* Michel could believe in a psychoanalytic, humanistic, biological, or behavioral approach to treating psychological problems. However, those who work to reduce stressors in the environment and in public domains such as schools are called community psychologists.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 2 that you answered correctly.

For each question you answered correctly, circle its number. (Quiz 1 numbers are not shaded; Quiz 2 numbers are shaded.) Are there patterns in the types of questions or the topics you got wrong that could direct your further study? Did you improve from Quiz 1 to Quiz 2?

CHAPTER 17

Social Cognition

MULTIPLE-CHOICE QUESTIONS

Sample Quiz 1

1. _____ are sets of people to whom we compare ourselves during self-evaluation.
 - a. Reference groups
 - b. Relative groups
 - c. Career groups
 - d. Out-groups
2. Cindy is preparing to switch from her public school to an exclusive private school for gifted student. Because Cindy won't be the smartest student any more, she will be more likely to experience _____ at the private school than at the public school.
 - a. cognitive dissonance

- b. the fundamental attribution error
 - c. relative deprivation
 - d. self-fulfilling prophecies
3. Compared to those with a differentiated self-schema, people with a unified self-schema are _____ to be vulnerable to feelings of failure in many areas of life just because they failed in one area.
- a. more likely
 - b. less likely
 - c. equally likely
 - d. Cannot be determined
4. "I am a Muslim," said Alaa. Alaa described his
- a. self-esteem.
 - b. self-schema.
 - c. social identity.
 - d. social perception.
5. On Gena's first day at work, she felt her boss didn't like her because he was short-tempered and gruff with her. From then on she was constantly prepared for more nasty comments. Gena's defensiveness irritated her boss further and caused him to be even more short-tempered. When Gena's boss gave her a negative six-month evaluation, it was most likely due to
- a. a stereotype.
 - b. prejudice.
 - c. a self-fulfilling prophecy.
 - d. discrimination.
6. Carol goes to a party to meet people. While there, she is introduced to Rico, an attractive man about her age. During their conversation, Rico is rude several times. Based on what you know about impression formation, which of the following is likely to be her response?
- a. Carol will assume that Rico is rude because he had a bad day.
 - b. Carol will assume that Rico is a rude person.
 - c. Carol is experiencing a self-fulfilling prophecy.
 - d. Carol will assume that Rico is similar to her and form a positive impression.
7. An attributional bias in which we attribute our failures to external causes and our successes to internal factors is called the
- a. actor-observer bias.
 - b. fundamental attribution error.
 - c. self-fulfilling prophecy.
 - d. self-serving bias.
8. Because she was an only child and was home-schooled in a sparsely populated rural area, Ellen never knew how intelligent she was until she was awarded a college scholarship. Why didn't she realize how smart she was prior to this?
- a. She had no one to compare herself to.
 - b. She had a unified self-schema.
 - c. She had a differentiated self-schema.
 - d. She suffered from relative deprivation.
9. When showing the campus to a group from India, Frasier mentions that many university alumni who received scholarships now contribute money to help others complete their degrees. Frasier comments that the alumni were repaying the favor. If the tour group is similar to the Hindu Indians described in your text, most of them are likely to believe that the alumni
- a. liked to help.
 - b. were repaying a favor.
 - c. have helpful personalities.
 - d. do not like to help, but feel forced to do so.

10. Julia is proud to be dating Vernon because he is thoughtful and considerate to everyone. He always sends her flowers and is willing to help his friends. Julia's friends are envious; none of their boyfriends is as considerate as Vernon. Vernon's behavior demonstrates _____ consensus, _____ consistency, and _____ distinctiveness. Julia will attribute his behavior to an _____ cause.
- high; high; high; external
 - high; low; high; internal
 - low; high; low; internal
 - high; high; low; external
11. Bridget and Jay just got into the car to go to lunch. Bridget asks Jay to wear his seatbelt, but he ignores her because he never gets into accidents. Which of the following best explains Jay's behavior?
- Cognitive dissonance
 - Unique invulnerability
 - Self-handicapping strategy
 - Self-serving bias
12. When Rosa heard the knock on her door, she looked out and saw a young man laughing heartily. She thought he must be good natured and friendly, and she opened the door to him. Rosa didn't know that the reason he was laughing was that he had just conned her neighbor out of \$500. Rosa had
- cognitive dissonance.
 - a faulty self-schema.
 - a fundamental attribution error.
 - a self-serving bias
13. Erik always says that looks are not important to him when he asks a woman out; however, recently he did not invite either of two women he liked to a dance because he didn't think they were attractive. When his friend points out the difference between what Erik said was important and what was really influencing him, Erik most likely experienced
- the actor-observer bias.
 - cognitive dissonance.
 - deindividuation.
 - the mere exposure effect.
14. Renato says that stereotyping occurs because people group others into social categories and see all members of a category as similar. Renato agrees with the _____ theory of prejudice.
- motivational
 - cognitive
 - contact
 - learning
15. Discomfort caused by attitude-behavior inconsistency tends to be
- influenced more by individual differences than by culture.
 - greater in collectivist cultures.
 - greater in individualist cultures.
 - about equal in all cultures.
16. Members of hate groups often act aggressively toward individuals whom their leaders identify as representing threats to the group's ideals. The members' behavior is best explained by _____ theories of prejudice.
- motivational
 - aversive racism
 - learning
 - cognitive
17. Which of the following is a good predictor of whether people will form a committed relationship?
- Similar attitudes
 - Similar degrees of attractiveness
 - Lack of conflict and anger

- d. Both (a) and (b)
18. Susan has just moved into a new dormitory. She will most likely become good friends with the women
- on the floor above hers.
 - in the dorm next door.
 - in the room next door.
 - at the other end of the hall.
19. With whom would you be most likely to fall in love at first sight?
- The person who surprises you with a \$1,000 car repair bill.
 - The person who fills your gas tank when you are in a hurry
 - The person you bump into on the quad on a beautiful spring day
 - There is an equal probability that you would fall in love with any of the above.
20. George and Louise share their thoughts, hopes, and daily worries and plan to stay married until death parts them. They enjoy an active and creative sex life. According to Sternberg's theory, George and Louise have _____ love.
- consummate
 - companionate
 - fatuous
 - romantic

Total Correct (See answer key) _____

Sample Quiz 2

Use this quiz to reassess your learning after taking Quiz 1 and reviewing the chapter.

1. Jack is depressed. He took a job in the city after completing graduate school on a scholarship and graduating with honors. Now that he is in the city, it seems that everyone is older, richer, and wiser than he is. Jack is experiencing
- cognitive dissonance.
 - relative deprivation.
 - role isolation.
 - a self-fulfilling prophecy.
2. Jack (see question 1) is depressed because he has changed his
- reference group.
 - relative group.
 - social identity.
 - self-schema.
3. Our social identity is our
- desire to be like our peers.
 - desire to be like our idols.
 - belief about our self-worth.
 - belief about the groups to which we belong.
4. The "possible self" is
- what a person actually is.
 - how many different roles one has.
 - what a person feels he or she could be.
 - None of the above
5. Even when things aren't going well for Wenlan in school, she feels good about herself. She and her partner, Chris, have been together for two years and have many close friends. Wenlan believes her academic problems don't reflect on her overall competence; therefore, she has a(n)
- differentiated self-schema.
 - unified self-schema.
 - dissonant self-concept.
 - consolidated self-esteem.

6. When Lance introduced himself to Nathan, he mentioned that he worked as a cashier in a supermarket. Nathan remembered all of Lance's comments about food and car repairs and remembered none of his comments about English poets and politics. Nathan's perception was most likely biased by
 - a. discrimination.
 - b. a schema.
 - c. social comparison.
 - d. the actor-observer bias.
7. According to the fundamental attribution error, we
 - a. always attribute our behavior to internal causes.
 - b. always make an internal attribution for our successes.
 - c. usually attribute others' behavior to external causes.
 - d. usually attribute others' behavior to internal causes.
8. People attribute behavior to an external cause when it has _____ consistency, _____ distinctiveness, and _____ consensus.
 - a. high; low; low
 - b. high; high; low
 - c. high; low; high
 - d. low; high; high
9. While finishing an exam, Sal looks around the room and notices that there are just two other students left. Though he has taken extra time because he is double-checking his answers, he assumes that the two students still working must not be very smart. The different explanations Sal uses for his own and for others' behavior illustrates
 - a. the fundamental attribution error.
 - b. the actor-observer bias.
 - c. unrealistic optimism.
 - d. self-perception theory.
10. While talking about her daughter Nicole, Clarissa says, "I have taught Nicole to be considerate, thoughtful, and moral, but Nicole's father is responsible for her inability to manage her money." This is an illustration of
 - a. the fundamental attribution error.
 - b. the self-serving bias.
 - c. the actor-observer bias.
 - d. relative deprivation.
11. Discrepancies between what we do and what we believe lead to
 - a. prejudice.
 - b. cognitive dissonance.
 - c. the fundamental attribution error.
 - d. relative deprivation.
12. George was in New Orleans for the Mardi Gras. He had never eaten raw oysters before and visited an oyster bar with his friends. When George discovered that he had eaten more than anyone else, he concluded that he must really like oysters. Which theory best explains George's attitude?
 - a. Cognitive dissonance theory
 - b. Elaboration likelihood theory
 - c. Social learning theory
 - d. Self-perception theory
13. When Mark sees a television commercial that shows a couple meeting and falling in love, he immediately phones the number they list to sign up for the dating service. Mark most likely used _____ to change his attitude.
 - a. a central route
 - b. a peripheral route
 - c. cognitive "busyness"
 - d. cognitive dissonance

14. Margie wants to reduce children's prejudices; therefore, she decides to run an after-school program in her grade school to bring together students of different backgrounds for games, study sessions, and snacks. Based on the description of successful intergroup contact given in the text, which of the following would bring Margie the most success?
- Allow the children to choose sides for a game of basketball.
 - Have the different ethnic groups describe their families' customs.
 - Design a project that will require all the children to cooperate in order to succeed.
 - Point out the errors of the high-status children.
15. Cognitive dissonance and the self-perception theory differ in that
- cognitive dissonance involves attitudes, whereas self-perception involves attribution.
 - cognitive dissonance involves attitude change, whereas self-perception involves social facilitation.
 - cognitive dissonance involves the reduction of internal tension, whereas self-perception does not.
 - None of the above
16. In-groups are similar to
- reference groups.
 - relative deprivation groups.
 - social facilitators.
 - none of the above.
17. Ed thinks prejudice and discrimination could destroy society. Ed is always fairly careful with his money, but he doesn't admit that he tends to check his change more carefully when the cashier is an African American. Ed's behavior fits best with the _____ theory of prejudice.
- motivational
 - cognitive
 - aversive racism
 - learning
18. Claudia and Kathy are good friends. Claudia likes Elizabeth, but Kathy does not. This difference in their attitudes creates problems when they try to plan social gatherings. Claudia and Kathy's relationship is
- balanced.
 - imbalanced.
 - dissonant.
 - distinctive.
19. According to Sternberg's triangular theory of love, the most mutually fulfilling type of love is
- romantic love.
 - companionate love.
 - consummate love.
 - any of the above.
20. Amanda and Roger are dating. They are likely to become committed to each other because they are similar in attractiveness, according to
- proximity effects.
 - reciprocal causality.
 - the matching hypothesis.
 - the mere exposure effect.
- Total Correct (See answer key) _____

ANSWERS TO MULTIPLE-CHOICE QUESTIONS

Circle the question numbers you answered correctly.

Sample Quiz 1

1. *a* is the answer. The groups that we compare ourselves to and we think of ourselves as belonging to are called reference groups. (see Social Comparison)
 - b*. Our relatives may form a reference group, but we are members of many groups and compare ourselves to many groups besides our relatives. Perhaps you were thinking of relative deprivation, in which a person feels a lack of something like money, due to a comparison with a well-off reference group.
 - c*. People who share the same career may form a reference group, but we also compare ourselves to many groups outside our profession.
 - d*. An out-group is any group of which we do not consider ourselves a member.
2. *c* is the answer. Going from being one of the best to being average can make a person feel sad for the loss of status, although an objective measure would show that Cindy is as smart as she ever was. (see Social Comparison)
 - a*. Cognitive dissonance is experienced when components of an attitude or attitudes and behaviors are not in line with each other.
 - b*. The fundamental attribution error is the tendency to believe that others' behaviors are caused by their personal characteristics rather than by the environment.
 - d*. Self-fulfilling prophecies occur when we allow our expectations to influence our actions, which, in turn, influence those around us into behaving as we expected.
3. *a* is the answer. (see Self-Schemas)
 - b, c, d*. Those with a unified self-schema feel that failure in one area of life implies failure in all others. Those with an undifferentiated self-schema isolate a failure in one area of life from all other unrelated areas.
4. *c* is the answer. A social identity is our set of beliefs about the groups to which we belong. Those groups may be religions, nationalities, or ethnic groups, to name a few. (see Social Identity Theory)
 - a*. Self-esteem is a positive or negative evaluation of how worthwhile we are. If Alaa had said, "I'm a worthless idiot" or "Gosh, I am a nice guy," he would be showing his level of self-esteem.
 - b*. A self-schema is a mental representation of oneself. We use social comparison and our social identity to construct our self-schema, but it can include situational factors, such as, "I'm shy at big parties, but open with my close friends."
 - d*. Social perception is a rather general term for how we interpret information about others and make inferences based on that information. It includes a mental representation of other people, but does not include the groups to which we personally belong.
5. *c* is the answer. Gena fulfilled her own prophecy. She was defensive because she expected her boss to be gruff. As a result, she elicited the boss's irritability and was given a negative evaluation. (see First Impressions)
 - a*. A stereotype is an impression of a group of people. Gena has formed a first impression about only one person: her boss.
 - b*. Prejudice is a preformed negative or positive judgment about a group of people. This would have been the correct answer only if Gena's first impression had led her to believe that all bosses were gruff and nasty.

- d.* Discrimination is the differential treatment of certain groups or individuals. If Gena's boss treated her negatively because she was female, black, lesbian, or pregnant, this example would demonstrate discrimination.
6. *b* is the answer. Negative acts such as being rude tend to heavily influence first impressions. Also, people assume that negative behavior reflects undesirable characteristics. Therefore, Carol will form a negative impression of Rico and probably assume that he is a rude person. (see First Impressions)
- a.* In forming first impressions, people tend to assume that negative acts are due to some undesirable characteristic of the person being evaluated. Carol is likely to assume that Rico is rude, rather than believe his behavior is the result of a bad day.
- c.* A self-fulfilling prophecy occurs when an already-formed first impression of another person elicits behavior that confirms that impression. Carol had no impression of Rico prior to their conversation at the party.
- d.* All else being equal, people assume that others are similar to themselves. Since people usually evaluate themselves positively, they also evaluate others positively. However, all else is not equal in this situation. Rico is rude to Carol. Since negative acts usually carry a lot of weight and are assumed to reflect negative characteristics, Carol will form a negative impression of Rico.
7. *d* is the answer. The self-serving bias is the belief that our behavior is responsible for our successes but not for our failures. (see Biases in Attribution)
- a.* The actor-observer bias is the tendency to attribute our own behavior to external causes and others' behavior to internal causes.
- b.* According to the fundamental attribution error, we are more likely to attribute other people's behavior to internal causes.
- c.* A self-fulfilling prophecy is not an attributional bias but a situation in which one person behaves toward another in a manner that elicits a response consistent with the person's initial expectations of the other.
8. *a* is the answer. According to Festinger's theory of social comparison, people learn about and evaluate themselves on such things as intelligence or attractiveness by comparing themselves to others. (see Social Comparison)
- b, c.* Ellen's mental representation of herself, which can be described in terms of unified or differentiated self-schemas, is not specifically addressed in this question.
- d.* Relative deprivation is the result of a negative comparison to a reference group. Ellen had no reference group while growing up.
9. *a* is the answer. The Hindu Indians in the cross-cultural experiment thought that reciprocal helpers enjoyed helping more than spontaneous helpers did. (see Explaining Behavior: Attribution)
- b.* The U.S. students were likely to see the reciprocal helping as externally caused.
- c.* The experimenters noted that Hindus in India tend not to distinguish between helping motivated by duty and helping motivated by personal traits.
- d.* Although the Hindu students believed that reciprocal helpers felt a moral responsibility to return a favor, they still thought the helpers liked to help.
10. *c* is the answer. Vernon's behavior has a low degree of consensus because not everyone is considerate and thoughtful. His behavior has a high degree of consistency because he is always considerate and thoughtful. His behavior has a low degree of distinctiveness because he is considerate and thoughtful toward all his friends. (see Explaining Behavior: Attribution)
- a, b, d.* Vernon's behavior could be attributed to external factors only if everyone was considerate and thoughtful (high consensus), if he was considerate only in a specific situation (high distinctiveness), and if he was not consistently considerate (low consistency).
11. *b* is the answer. Jay is unrealistically optimistic as a result of thinking that he is invulnerable. (see Self-Protective Functions of Social Cognition)

- a.* Cognitive dissonance occurs when components of an attitude do not match up and cause discomfort. There is nothing in the story to suggest that Jay feels uncomfortable, for example, because his cognitive component doesn't match his behavioral component.
- c.* People using the self-handicapping strategy behave in a less than efficient or healthy way so that they have an excuse when they fail.
- d.* The self-serving bias is manifested when a person takes credit for success but not for failure.
12. *c* is the answer. Rosa attributed the man's behavior to internal factors, such as personality traits. She did not consider external reasons for his laughter. (see Biases in Attribution)
- a.* This is a theory of attitude change. Rosa was explaining the cause of a behavior.
- b.* A self-schema would consist of Rosa's ideas about herself. The idea she is displaying here concerns the man at her door.
- d.* The self-serving bias is a tendency to take personal credit for success but to blame external causes for failure. It does not apply here.
13. *b* is the answer. When our behavior doesn't match our beliefs (cognitive component), we feel uncomfortable and motivated to change either the attitude or the behavior. (see Changing Attitudes)
- a.* The actor-observer bias has to do with attributing behavior to external versus internal causes; it doesn't deal with disagreement between components of an attitude.
- c.* Deindividuation, which is discussed in Chapter 18, is the feeling of losing oneself in a crowd.
- d.* The mere exposure effect occurs when people who see each other often are more likely to become friends.
14. *b* is the answer. The cognitive theory of prejudice suggests that we use schemas and cognitive shortcuts such as social categories. (see Theories of Prejudice and Stereotyping)
- a.* The motivational theory of prejudice proposes that people with authoritarian personalities have a tendency to obey people of higher status and discriminate against people of lower status.
- c.* The contact hypothesis is not a theory of prejudice, but it is based on the cognitive and learning theories.
- d.* Learning theory emphasizes that observational learning and operant conditioning can teach children about stereotypes and prejudice.
15. *c* is the answer. Individualist cultures encourage consistency between self-concept and behavior. If this consistency is not demonstrated, one may be derogatorily labeled a hypocrite. (see Changing Attitudes)
- a, d.* Research suggests that there are cross-cultural differences.
- b.* Collectivist cultures may exhibit less discomfort because behaving differently than one feels is acceptable if it contributes to group harmony.
16. *a* is the answer. Motivational theories suggest that people with the trait of authoritarianism act aggressively toward those who are identified as threats by authority figures. (see Theories of Prejudice and Stereotyping)
- b.* Aversive racism suggests that negative attitudes toward out-groups may be expressed even by those who do not consider themselves prejudiced. Members of hate groups would not fall into this category.
- c.* Learning theories, which propose that people learn prejudice by watching others, is not demonstrated in this question.
- d.* Cognitive theories emphasize that the cognitive structures we use to make sense of our social world can contribute to prejudice.
17. *d* is the answer. Frequent contact, similar attitudes, and similar attractiveness are associated with positive relationships. (see Keys to Attraction)
- a.* *b* is also the answer.
- b.* *a* is also the answer.

- c.* Conflict and anger are part of any relationship. The successful resolution of conflict and anger is indicative of a positive relationship.
18. *c* is the answer. Research has shown that next-door neighbors are more likely to become good friends than are people who live at opposite ends of the hall or farther away. (see Keys to Attraction)
- a. b. d.* People tend to like those with whom they have the most contact. Susan will probably have more contact with the women living next door.
19. *c* is the answer. You are much more likely to be attracted to people if you meet them in a comfortable setting. (see Keys to Attraction)
- a.* You probably would not associate a person who hands you a bill for \$1.000 with pleasant circumstances.
- b.* If you were in a hurry, you would not have sufficient contact with a gas station attendant.
- d.* You would be more attracted to the person you met in comfortable physical surroundings.
20. *a* is the answer. George and Louise's relationship has a high level of intimacy, commitment, and passion. (see Intimate Relationships and Love)
- b.* Companionate love is low on passion but high on intimacy and commitment.
- c.* Fatuous love is high on passion and commitment but low on intimacy.
- d.* Romantic love is high on passion and intimacy but low on commitment.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 1 that you answered correctly.

Sample Quiz 2

Circle the question numbers you answered correctly.

1. *b* is the answer. Although Jack isn't truly "deprived," he is experiencing deprivation compared to what he was used to before. (see Social Comparison)
- a.* Cognitive dissonance is the product of conflicting attitudes.
- c.* There is no such thing as role isolation.
- d.* A self-fulfilling prophecy is an impression that elicits behavior confirming the impression. Jack's impressions are not making him depressed. His standing in comparison to others' in his new reference group is making him unhappy.
2. *a* is the answer. Jack had a lot of status in his old reference group of students. Now that he is a member of a new group, it will take time to improve his standing in comparison to the other group members. His low status at present is making him depressed. (see Social Comparison)
- b.* Our relatives may form a reference group. But we are members of many groups and compare ourselves to many groups besides our relatives.
- c.* He probably still considers himself a member of the same religion, nation, and ethnic group.
- d.* The story doesn't describe whether Jack has a differentiated or a unified self-schema and doesn't indicate that it changed.
3. *d* is the answer. Our social identity is our belief about our membership in groups. (see Social Identity Theory)
- a. b.* We may want to be like our peers or idols, but *d* is the best answer.
- c.* Self-esteem is our belief about our self-worth.
4. *c* is the answer. (see Self-schemas)
- a.* The "present" self is what a person actually is.
- b.* Differentiated self-schemas include how many roles one has.
- d.* The answer is *c*.

5. *a* is the answer. Wenlan thinks of herself as having different attributes in different situations. (see Self-schemas)
 - b*. If Wenlan had a unified self-schema, she would feel badly about her whole life when her academic performance was poor.
 - c, d*. There is no such thing as dissonant self-concept or consolidated self-esteem.
6. *b* is the answer. When Nathan thought about Lance's job, it most likely activated a schema for cashiers or supermarket workers that didn't include interests in poetry and politics. (see The Role of Schemas)
 - a*. Discrimination is the behavioral component of a prejudicial attitude, but it does not bias memory.
 - c*. Social comparison is the process by which we compare ourselves to others. Nathan may have been comparing himself to Lance, but it was not an influence on his memory.
 - d*. The actor-observer bias relates to internal versus external attributions, not memory for personal information.
7. *d* is the answer. According to the fundamental attribution error, we usually attribute others' behavior to internal causes. (see Biases in Attribution)
 - a*. According to the fundamental attribution error, we attribute others' behavior to internal causes.
 - b*. According to the self-serving bias, we attribute our successes to internal causes.
 - c*. According to the fundamental attribution error, we usually attribute others' behavior to internal, not external, causes.
8. *d* is the answer. Low consistency, high consensus, and high distinctiveness would lead to an external attribution. (see Explaining Behavior: Attribution)
 - a, b, c*. High consistency means that a person always behaves in a similar manner. Low consensus means that not many people display a particular behavior. Low distinctiveness means that the behavior occurs in many situations. These features would lead one to attribute someone's behavior to an internal cause: that person often displays the behavior in many situations, whereas other people do not. The behavior is probably due to a characteristic of the person, not to an external cause.
9. *b* is the answer. The actor-observer bias occurs when we make a comparison. We attribute our own behavior to external factors (just checking) but assert that others' behavior is due to internal factors (not being very smart). (see Biases in Attribution)
 - a*. The fundamental attribution error does not involve an attribution about ourselves. It is a tendency to ascribe others' behavior to internal factors. If Sal simply made an observation about the other students and did not explain his own behavior in terms of external causes, this answer would apply.
 - c*. Unrealistic optimism is the tendency to believe that positive events are more likely to happen to oneself than to others. It does not apply here.
 - d*. Self-perception involves determining attitudes from behaviors. This question concerns differential explanations for a behavior.
10. *b* is the answer. According to the self-serving bias, we take credit for success but blame external causes for failure. Nicole's mother is taking credit for Nicole's good habits and qualities but not for her bad ones. (see Biases in Attribution)
 - a*. According to the fundamental attribution error, Nicole's mother should attribute Nicole's behavior to Nicole's internal characteristics. Instead, she believes that the causes of Nicole's behavior are her and her husband's style of raising their daughter (characteristics that are external to Nicole).
 - c*. The actor-observer bias is the tendency to attribute our own behavior to an external cause. Nicole's mother is making attributions about Nicole's behavior, not her own.
 - d*. People experience relative deprivation when they compare themselves to others who have a higher standard of living.
11. *b* is the answer. Cognitive dissonance is internal tension due to conflicting attitudes or components of attitudes. (see Changing Attitudes)

- a. Prejudice is a preformed negative or positive attitude toward an entire group of people. Stereotypes can lead to prejudice.
 - c. The fundamental attribution error refers to mistakes made in explaining the causes of behavior.
 - d. Relative deprivation occurs when, as a new member of a reference group, a person's standing in comparison to others is low.
12. *d* is the answer. According to self-perception theory, we look for clues in our actions when we have no attitude about something. Since George had eaten so many oysters, he concluded that he must like them. (see Changing Attitudes)
- a. Cognitive dissonance results from inconsistency between belief and behavior. An attitude must already exist before there can be cognitive dissonance.
 - b. The elaboration likelihood model provides an explanation for attitude change. George is forming a new attitude in this question, not changing an old one.
 - c. Social learning theory from the chapter on learning suggests that we learn much by observing the behavior of others. (See Chapter 6 to review this topic.)
13. *b* is the answer. Mark is not thinking critically about the dating service. He is using appearances (happy couples) to make his decision. (see Changing Attitudes)
- a. A central route would be one that considers the content of the message to be more important than the communicator.
 - c. Cognitive "busyness" occurs when we are involved in thinking about something other than the decision to be made. It makes a peripheral route to decision-making more likely. Mark is not described as being busy thinking about something else.
 - d. Cognitive dissonance occurs when thoughts, behaviors, and attitudes are inconsistent with one another.
14. *c* is the answer. Cooperation is an important factor in determining the success of contact in reducing prejudice. Activities like the jigsaw technique often help reduce prejudice. (see Reducing Prejudice)
- a, d. A sports competition or the singling out of a few individuals will probably not reduce prejudices and, in fact, may worsen them.
 - b. A presentation of information may help students understand each other, but it won't be as effective as having the students cooperate.
15. *c* is the answer. Cognitive dissonance, unlike self-perception, involves internal tension caused by discrepant or conflicting attitudes. According to self-perception theory, people who are unsure about their attitudes examine their past behavior to determine them. This does not involve any uneasiness or internal tension. (see Changing Attitudes)
- a. Cognitive dissonance and self-perception theory both involve attitudes.
 - b. Self-perception does not involve social facilitation.
 - d. *c* is the answer.
16. *a* is the answer. An in-group is any category of people of which we consider ourselves a member. (see Theories of Prejudice and Stereotyping)
- b. There is no such thing as a relative deprivation group. Relative deprivation occurs when our standing in comparison to members of a reference group is low.
 - c. There is no such thing as a social facilitator. Social facilitation occurs when the presence of other people improves performance.
 - d. *a* is the answer.
17. *c* is the answer. The theory of aversive racism suggests that even people who are disgusted by prejudice may sometimes show it. This theory supports the idea that racism is so ingrained in us that sometimes we may not even realize we are showing it. (see Thinking Critically: Is Ethnic Prejudice Too Ingrained Ever to Be Eliminated?)

- a.* The motivational theory emphasizes how personality can make us more or less likely to look for status differences between ourselves and others.
 - b.* The cognitive theory of prejudice states that prejudice may result from the social-cognitive processes people use in dealing with the world.
 - d.* Learning theory suggests that children acquire prejudice by watching others.
18. *b* is the answer. A relationship is imbalanced if friends disagree on their evaluation of a third person. (see Keys to Attraction)
- a.* In a balanced relationship, friends agree on their evaluation of a third person.
 - c.* Perhaps you were thinking of cognitive dissonance. It deals with disagreement in one person's attitudes, behaviors, and feelings.
 - d.* Relationships are not rated on distinctiveness; behaviors are. In addition, we don't know if Claudia and Karen's behavior is distinctive without having information about their behavior toward many other people.
19. *c* is the answer. Consummate love, which consists of high levels of passion, intimacy, and commitment, is the most mutually satisfying type of love. (see Intimate Relationships and Love)
- a.* Romantic love is composed of high levels of passion and intimacy but low levels of commitment.
 - b.* Companionate love is characterized by intimacy and commitment but lacks passion.
 - d.* Although all types of love have their advantages, only consummate love has passion, intimacy, and commitment.
20. *c* is the answer. The matching hypothesis states that people tend to form committed relationships with people who are similar in physical attractiveness. (see Keys to Attraction)
- a.* Proximity makes relationships more likely to form when people see each other often.
 - b.* Reciprocal causality is the term used when attraction is both a cause and a consequence of similarity.
 - d.* The mere exposure effect is the reason for the effect of proximity.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 2 that you answered correctly.

For each question you answered correctly, circle its number. (Quiz 1 numbers are not shaded; Quiz 2 numbers are shaded.) Are there patterns in the types of questions or the topics you got wrong that could direct your further study? Did you improve from Quiz 1 to Quiz 2?

CHAPTER 18

Social Influence

MULTIPLE-CHOICE QUESTIONS

Sample Quiz 1

1. People sometimes behave with fewer inhibitions when they are in a group than when they are alone. This phenomenon is called
 - a. diffusion of responsibility.
 - b. deindividuation.
 - c. situation ambiguity.
 - d. social facilitation.

2. Everyone felt very uncomfortable when Ashley kept smiling during a funeral. Ashley's smiling defied
 - a. deindividuation.
 - b. social facilitation.
 - c. social loafing.
 - d. a norm.
3. Nina's auto racing time has not improved in days. Although she knows the course well, she is no longer improving. To increase her speed, Nina should
 - a. have someone race against her.
 - b. eject her staff and race the course without anyone recording times.
 - c. combat deindividuation.
 - d. reduce the bystander effect.
4. Shawn's instructor doesn't observe or grade student study group behavior; therefore, Shawn sits back and listens to the other students. Shawn is exhibiting social
 - a. facilitation.
 - b. impairment.
 - c. loafing.
 - d. penalty.
5. Conformity is highest
 - a. when the stimulus is unambiguous.
 - b. when unanimity exists.
 - c. in men.
 - d. in women.
6. Li is traveling in France. As he walks into his hotel, he notices everyone handing ten francs to the doorman. Li also hands the doorman ten francs. This is an example of
 - a. conformity.
 - b. compliance.
 - c. obedience.
 - d. social facilitation.
7. In the foot-in-the-door technique,
 - a. larger and larger requests are made.
 - b. a straightforward request is made.
 - c. a very large request is made, followed by a smaller one.
 - d. the original commitment is devalued, and a request is made for more.
8. Ethan has just joined a new group of friends. They want to break windows at the back of the school building for fun. Ethan protests, but the group keeps saying, "Aw, why not come with us? Are you a chicken?" He finally decides to go along with the group; therefore, Ethan has
 - a. conformed.
 - b. complied.
 - c. obeyed.
 - d. competed.
9. Colleen wants to get one day off work during final exam week but knows that her boss won't be too happy about the idea. Colleen explains that she really needs to study and asks for the whole week off. After the boss refuses, she asks for the one day off she originally wanted. Colleen has used the
 - a. conformity method.
 - b. door-in-the-face technique.
 - c. foot-in-the-door technique.
 - d. obedience method.
10. Obedience is
 - a. conformity to a request.
 - b. private acceptance of a suggestion.
 - c. yielding to a command from an authority figure.
 - d. a response to aggressive behavior.

11. Diffusion of responsibility occurs when
 - a. many people are present when someone needs help.
 - b. groups try to make decisions.
 - c. a leader divides work equally among his or her staff.
 - d. people do not take responsibility for aggressive acts.
12. Which is *not* true of the relationship between pornography and aggression?
 - a. Portrayals of violence affect attitudes toward aggression.
 - b. Men are more aggressive toward women but not toward men after viewing aggressive pornography.
 - c. Some rapists become aroused after viewing aggressive pornography.
 - d. All of the above are true.
13. Agatha is moving to Miami Beach, Florida, to begin her career. She wants to find a very safe apartment to live in. Which of the following should she choose?
 - a. An area near the airport because her job requires her to travel quite a bit
 - b. An area that has zoning laws restricting the number of occupants per building
 - c. An apartment building with no air conditioning
 - d. An area near the plant where she works, despite the smell
14. According to the arousal: cost-reward theory, Darlene will be most likely to help the lost child crying in the mall if she
 - a. is related to the child.
 - b. is very worried for the child's safety and has the time to help.
 - c. has been to the mall many times.
 - d. knows what it feels like to be a lost child.
15. Dean doesn't properly maintain his car's exhaust system due to the expense. If everyone behaved like Dean, the air pollution would become unbearable; therefore, Dean's situation is an example of a(n)
 - a. analogue experiment.
 - b. prisoner's dilemma.
 - c. social dilemma.
 - d. zero-sum game.
16. Brian is very stressed because the deadline is nearing and he needs to discuss a group project with his classmate Kevin, who keeps ignoring him. When Brian suggests a meeting time, Kevin tells him that a meeting is impossible. Brian then pushes Kevin against a wall and rips up his appointment book. Brian's behavior best fits the _____ of aggression.
 - a. biological theory
 - b. deindividuation theory
 - c. frustration-aggression hypothesis
 - d. social dilemma hypothesis
17. Tim and Jill are medical students. At the beginning of the semester, Tim does not let Jill borrow his notes. When Tim asks Jill for her notes, she won't let him borrow them. Before the midterm exam, though, he calls her and offers his notes and assistance. Before the final exam, Jill offers her notes and assistance. Tim and Jill are employing which strategy?
 - a. Tit-for-tat
 - b. Low-ball
 - c. Altruism
 - d. Foot-in-the-door
18. Darrell's and Tomer's softball teams have a friendly rivalry. Because only one team can win, they often try to distract each other while competing. Darrell and Tomer are participating in a(n)
 - a. injunctive norm.
 - b. prisoner's dilemma.
 - c. tit-for-tat strategy.
 - d. zero-sum game.

19. Bernadette is a task-oriented leader. She would be most suited to lead in which type of job?
- Assigning people to duties that fit their abilities
 - Getting a report out to the boss as quickly as possible
 - Managing people who are not familiar with their jobs
 - All of the above
20. Wing, the president of the student council, wants to reduce the likelihood of groupthink. In order to be successful, he should
- isolate the group from other student groups.
 - forcefully explain his position before allowing others to contribute ideas.
 - suggest that everyone contribute suggestions anonymously.
 - use task-oriented leadership.

Total Correct (See answer key) _____

Sample Quiz 2

Use this quiz to reassess your learning after taking Quiz 1 and reviewing the chapter.

- Why do norms influence behavior to such a great degree?
 - They allow us to predict the behavior of others.
 - They let us know which behaviors will be rewarded.
 - They let us know how to behave in new situations
 - They do all of the above.
- At the football game, Luis felt swept up in the excitement and rushed onto the field with the rest of the fans. If Luis had thought things through, he would not have helped the mob push over the goal posts, but he experienced
 - deindividuation.
 - diffusion of responsibility.
 - social facilitation.
 - compliance.
- Claudette is a piano major. She has been practicing for her end-of-the-semester performance for four months and has the music memorized. At her lessons, however, she plays lackadaisically. Her teacher wants to prepare her for her performance and arranges to have a few faculty members come to Claudette's next lesson to hear her play. Claudette plays flawlessly. What do you think happened?
 - Social facilitation
 - Social impairment
 - Social enhancement
 - Social diffusion
- Lori's bridesmaids like the pink backless dress, but Lori does not. Although no one actually asks her to concede, she decides to go along with the crowd and choose that dress. Lori has exhibited
 - conformity.
 - compliance.
 - consensus.
 - None of the above
- Ambiguous social situations facilitate which of the following?
 - Diffusion of responsibility
 - Conformity
 - Use of norms to guide behavior
 - All of the above
- Myron wants his secretary to stay late. He gets her to agree to stay until 7 p.m. and then tells her that it will not do him any good unless she stays until 10 p.m. This is called the _____ technique.
 - foot-in-the-door
 - door-in-the-face
 - low-ball
 - tit-for-tat

7. Sherry is in a jam. She needs a place to stay in New York while she looks for a job. Several weeks before her trip, she calls a friend and asks if she can stay for a night. Once Sherry arrives, she asks if she can stay for several days. On the second day, she asks if she can stay for an entire week. Sherry is employing which method of compliance?
 - a. Zero-sum game
 - b. Tit-for-tat strategy
 - c. Low-ball technique
 - d. Foot-in-the-door technique
8. Mai Ling is a veteran emergency room nurse. The doctor in charge, who has been on duty for twenty-four hours without a break, has ordered her to administer the wrong drug to a patient. She knows that if she obeys the doctor's order, the patient will die. Under which circumstances will she be *least* likely to obey?
 - a. If she also has been on duty for twenty-four hours without a break
 - b. If she has an external locus of control
 - c. If there are other nurses in the room who will also disobey
 - d. If she has an authoritarian personality
9. Which of the following conclusions was derived from Milgram's studies of obedience?
 - a. Even ordinary people, with no particular hostility, under certain circumstances are capable of brutal acts toward other people.
 - b. Most people are able, under the proper circumstances, to suppress their natural aggressiveness.
 - c. The need to be accepted by others is a powerful motivating force.
 - d. When individuals lose their sense of identity in a group, they often become more aggressive.
10. Who among the following is *most* likely to behave aggressively?
 - a. Luis, who just finished exercising.
 - b. Celia, who is watching a television program with violent content.
 - c. Ofar, who is in a bad mood.
 - d. Matt, who just finished watching a film with a lot of nudity.
11. Donna is concerned because her six-year-old twins have begun kicking each other and their playmates. She decides not to let them watch any more violent cartoons. Donna's decision is in agreement with which approach to aggression?
 - a. Biological
 - b. Learning
 - c. Frustration-aggression hypothesis
 - d. Instinct
12. Which of the following summarizes the evolutionary view of helping behavior?
 - a. People feel good when they help others.
 - b. People display helping behaviors to protect the gene pool.
 - c. People want to protect other individuals.
 - d. People learn to be helpful.
13. What is meant by the bystander effect?
 - a. People are likely to gather at the scene of a serious accident when they see others present.
 - b. People are likely to gather at the scene of a tragedy and hinder rescue operations.
 - c. People are more likely to provide aid when there are helping models present.
 - d. People are less likely to provide help when there are other witnesses to a tragedy.
14. Which of the following is an example of a resource dilemma?
 - a. If not enough people watch a television program, advertisers will no longer sponsor it.
 - b. If everyone watches noncommercial public television but no one contributes money for its support, it will go off the air.
 - c. Apartment dwellers need to pitch in to buy a high-powered television antenna for their building.
 - d. If two people keep competing instead of cooperating, they will both lose.
15. The shelter for homeless people has a large number of volunteers who were once homeless. When such volunteers are asked why they contribute so much to the shelter, they often say it's because they know

what it feels like to be without a home. Their explanation fits best with the _____ theory of helping.

- a. arousal: cost-reward
 - b. empathy-altruism
 - c. environmental
 - d. evolutionary
16. The tit-for-tat strategy involves being competitive
- a. in response to competition.
 - b. in response to cooperation.
 - c. after initiating cooperation.
 - d. after initiating competition.
17. If two community service organizations want to reduce the conflict between groups, the best course of action would be to
- a. find a common community service goal.
 - b. ensure that each individual's contributions are noted and rewarded.
 - c. keep members from discussing issues outside of meetings.
 - d. start a contest to see which group can raise the most money for their projects.
18. Which of the following is *most* likely to cause interpersonal conflict?
- a. A tit-for-tat strategy
 - b. The fundamental attribution error
 - c. Groupthink
 - d. A superordinate entity
19. Karen is the coordinator of all the psychology teachers. She asks for opinions and suggestions from all the teachers regarding any task the group must accomplish. What style of leadership is she using?
- a. Tit-for-tat
 - b. Person-oriented
 - c. Task-oriented
 - d. Authoritative
20. The phenomenon of poor decision making in closely knit groups with strong leaders is called
- a. deindividuation.
 - b. groupthink.
 - c. social loafing.
 - d. social impairment.

Total Correct (See answer key) _____

ANSWERS TO MULTIPLE-CHOICE QUESTIONS

Circle the question numbers you answered correctly.

Sample Quiz 1

1. *b* is the answer. Deindividuation occurs because people feel they won't be held accountable for their actions. (see Social Influence)
 - a.* Diffusion of responsibility means that the more people there are in a crowd, the less likely each individual is to help someone in need.
 - c.* There is no such phenomenon as situation ambiguity.
 - d.* Social facilitation occurs when the presence of others increases performance.
2. *d* is the answer. When Ashley violated a norm, it made the people around her uncomfortable. Usually the person breaking the social rule also feels uneasy. (see Social Influence)

- a.* Deindividuation is losing oneself in the group action, as in a mob.
 - b.* A person experiencing social facilitation performs better while people are around than when alone.
 - c.* Social loafing occurs when a person in a group doesn't do his or her share of the work.
- 3. *a* is the answer. When a task is well-rehearsed, people often perform better with others present. If Nina knows the course well, then having someone race her may be the motivation she needs to push herself to drive her best. (see Social Influence)
 - b.* A well-rehearsed activity is not usually harmed by the presence of others; therefore, such social impairment shouldn't be a factor for Nina.
 - c.* Deindividuation is feeling "swept up" by the mood of a crowd.
 - d.* The bystander effect is related to diffusion of responsibility, which is the hesitance of people to help when others are around. Each person puts the responsibility of helping on the other bystanders.
- 4. *c* is the answer. Shawn is not making much of an effort because he doesn't believe his behavior in the group is being monitored. (see Social Influence)
 - a. b.* Social facilitation and social impairment relate to behaviors on which we think we might be evaluated. Social facilitation is when others' presence improves performance; social impairment is when others' presence worsens performance.
 - d.* Social penalty is not one of the concepts discussed in this chapter.
- 5. *b* is the answer. When everyone else has the same view, it is more likely that another person will conform. (see Conformity and Compliance)
 - a.* An unambiguous stimulus would be less likely to cause conformity, because people would be more sure of their decisions and not have to rely on others for cues.
 - c. d.* No gender differences in conformity have been found when the situations were equally familiar.
- 6. *a* is the answer. Li, as a result of unspoken pressure, is conforming. (see Conformity and Compliance)
 - b.* If someone had suggested that he give the doorman ten francs, this would have been the correct alternative.
 - c.* If someone in authority had demanded that he give the doorman ten francs, this would have been the correct alternative.
 - d.* Social facilitation occurs when an activity goes better while others are present. This doesn't relate to Li's situation.
- 7. *a* is the answer. (see Conformity and Compliance)
 - b.* Asking for something is a request, not a technique for inducing compliance.
 - c.* The door-in-the-face technique involves making a large request, having it denied, and then making a smaller request.
 - d.* The low-ball technique occurs when a person claims the original commitment won't work and asks for more.
- 8. *b* is the answer. Ethan is changing his behavior in response to expressed (spoken) social influence. (see Conformity and Compliance)
 - a.* Conformity occurs when people change their behavior in response to real or imagined unspoken peer pressure.
 - c.* Ethan's friends are not authority figures who demanded that he go along with them; they just applied social pressure.
 - d.* Ethan was not in competition with his friends; they were asking him to go with them.
- 9. *b* is the answer. Colleen has asked for something she knows her boss can't give her. She believes that the boss will feel badly for refusing her first request and will go along with her second, more realistic, request. (see Conformity and Compliance)
 - a.* Conformity is going along with unspoken pressure; there is no "conformity method."

- c. The foot-in-the-door technique would be the reverse of what Colleen tried. She might ask for a few hours off (make a small request), then see if the boss would be willing to give her the whole day off (a slightly larger request).
- d. Colleen's boss has more authority than she has; therefore, she is not demanding obedience. There is no such thing as "obedience method."
10. c is the answer. Obedience occurs when people yield to a demand, rather than a request, because they think they must. (see Obedience)
- a. Conformity results from unspoken group pressure, not a request.
- b. People can and do comply without accepting or agreeing with the suggestion.
- d. Obedience is not a response to aggression.
11. a is the answer. When many people are present, diffusion of responsibility occurs, and helping behavior is reduced. (see Aggression)
- b. Diffusion of responsibility is not related to group decision making. (You may be thinking of groupthink, the inability of a small, closely knit group to evaluate realistically the decisions it makes.)
- c. Diffusion of responsibility is related to helping behavior, not to leadership styles.
- d. Diffusion of responsibility is related to helping behavior, not to aggression.
12. d is the answer. Portrayals of violence do alter attitudes toward violence, arouse some rapists, and cause an increase in men's aggression toward women but not toward other men. (see Aggression)
13. b is the answer. As crowding increases, so does aggression. Living in an area where zoning laws limit crowding would be safer than living in any of the other alternatives. (see Altruism and Helping Behavior)
- a. Living near the airport will increase the noise in Agatha's neighborhood. Unwanted noise has been associated with increases in aggression.
- c. High temperature is correlated with aggression. Miami Beach, which normally has a warm climate, can become oppressively hot during the summer months. If people have no way to escape the heat, they may behave aggressively.
- d. Air pollution raises levels of aggression.
14. b is the answer. Once a person is upset by another's misfortune, the person will weigh the costs of helping versus not helping. Darlene is upset and the cost of helping is not very high. (see Altruism and Helping Behavior)
- a. This would be an evolutionary view of why people help.
- c. Being familiar with an area may increase helping behavior, but this is not part of the arousal: cost-reward theory.
- d. The empathy-altruism model proposes that helping is often a result of empathy.
15. c is the answer. What is economically beneficial for Dean would be terrible for the environment if everyone did it. (see Cooperation, Competition, and Conflict)
- a. An analogue experiment was used to study the evolutionary approach to helping behavior. It was called analogue because the people were asked to imagine their reactions to hypothetical situations, rather than being placed in those situations. Dean is not in an analogue experiment.
- b. A prisoner's dilemma occurs when two people are differentially rewarded for cooperating or competing. The greatest number of individual wins results from one person choosing a competitive response and the other person choosing a cooperative response. The greatest number of overall wins results from cooperation. The smallest number of overall wins results from both people making a competitive response.
- d. In a zero-sum game, only one person can win. If Dean were to properly maintain his car, other people would *not* automatically have something taken away; therefore, this is not a zero-sum game.
16. c is the answer. Brian was stressed out by Kevin's lack of cooperation and, therefore, was more likely to behave aggressively toward Kevin. (see Aggression)

- a.* Biological theories of aggression would cite high testosterone levels or damage to certain brain areas as the cause of aggression. Brian's physiological state is not described.
 - b.* Deindividuation is the sense that one won't be held responsible for actions committed while in a crowd of people. Brian is not in a crowd; he could easily be identified as the person who assaulted Kevin. There is no such thing as deindividuation theory.
 - d.* A social dilemma involves making a decision about an action that will take some investment of time, effort, or money versus an action that is easier but more harmful to the society as a whole. Social dilemmas are situations, not hypotheses.
17. *a* is the answer. The tit-for-tat strategy involves punishing competitive moves with competition and rewarding cooperative moves with cooperation. (see Cooperation, Competition, and Conflict)
- b.* The low-ball technique is used to increase compliance by first getting a commitment and then devaluing that commitment and making an even larger request.
 - c.* Altruism is the desire to help someone without an external incentive. Neither Tim nor Jill freely shares notes; they are making an exchange.
 - d.* The foot-in-the-door technique involves making gradually larger and larger requests.
18. *d* is the answer. In a zero-sum game, when one person wins, the other must lose. (see Cooperation, Competition, and Conflict)
- a.* An injunctive norm is a guide to what a person should do. An example of following the injunctive norm of reciprocity is giving a present to someone in return for a present.
 - b.* In the prisoner's dilemma, a person can gain by cooperating. It is not a situation where only one can win at the others' expense.
 - c.* The tit-for-tat strategy may be used when cooperation is possible, unlike this game, where only one team can win.
19. *d* is the answer. The task-oriented style of leadership works best when people need to be assigned duties, when time is short, or when workers are unfamiliar with their jobs. (see Group Processes)
20. *c* is the answer. When people hear others all pushing for the same idea, they are more hesitant to disagree. If suggestions were made anonymously, perhaps more ideas would be proposed. (see Group Processes)
- a, b.* Group isolation and leaders who take a firm stand contribute to groupthink.
 - d.* Task-oriented leadership would mean that Wing would give instructions rather than consult the group, but it would not improve the choices made, nor would it make groupthink unlikely. Wing might still feel he had the support of the group for the ideas he was directing them to carry out.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 1 that you answered correctly.

Sample Quiz 2

Circle the question numbers you answered correctly.

- 1. *d* is the answer. Norms make us more comfortable because we know what to expect from others and how to behave. (see Social Influence)
- 2. *a* is the answer. Much of mob behavior can be explained by the loss of personal identity that comes with getting caught up in the group mentality. (see Social Influence)
 - b.* Diffusion of responsibility is the spreading around of responsibility for helping when many people see someone in need.
 - c.* Social facilitation occurs when our performance benefits from the presence of other people. Luis is just going along with the mob, not improving a personal performance.
 - d.* Luis is not complying with a request, he is conforming to the riotous behavior of others.
- 3. *a* is the answer. We become aroused in the presence of others. Dominant or well-rehearsed behaviors are usually performed better under these circumstances. (see Social Influence)

- b.* If Claudette was playing a particularly difficult piece that she did not know well, this would have been the answer.
- c, d.* There is no such thing as social enhancement or social diffusion.
4. *a* is the answer. Conformity occurs when people, in the face of unspoken peer pressure, change their behavior to match that of other group members. (see Conformity and Compliance)
- b.* Compliance occurs when people change their behavior because of expressed social influence.
- c.* When people's behavior is based on their beliefs and happens to match that of other people, consensus exists.
- d.* *a* is the answer.
5. *d* is the answer. (see Conformity and Compliance)
- a, b, c.* In an ambiguous situation, people let norms guide their behavior, tend to conform, and are less likely to help because they do not clearly recognize the need for help.
6. *c* is the answer. Myron first got his secretary to agree to stay late. Then he said staying late would do him no good unless she stayed very late. (see Conformity and Compliance)
- a.* The foot-in-the-door technique involves starting out with a small request, which is complied with, and then making larger and larger ones. The secretary did not have a chance to comply with the first request; instead, it was labeled as unhelpful.
- b.* The door-in-the-face technique involves first making a very large request, which is usually refused, and then making a smaller request. The smaller request is usually granted.
- d.* The tit-for-tat technique rewards cooperation with cooperation, but punishes competition with competition.
7. *d* is the answer. Sherry is gradually making larger and larger requests, which represents the foot-in-the-door technique. (see Conformity and Compliance)
- a, b.* The tit-for-tat strategy and zero-sum game are competitive. Sherry is not competing with her friend.
- c.* The low-ball technique involves getting an original commitment, not allowing compliance by devaluing that commitment, and asking for more. Instead, Sherry is gradually asking for more and more after her friend has complied with previous requests.
8. *c* is the answer. The presence of others who will also disobey would be the most powerful factor in reducing obedience in this example. (see Obedience)
- a.* If Mai Ling is overtired, her mental processing will probably be impaired. She would be more likely to follow routine and obey—without thinking about consequences.
- b, d.* People who have an external locus of control and people high in authoritarianism are more likely than others to obey.
9. *a* is the answer. (see Obedience)
- b, c.* Both of these statements are true, but they do not derive from Milgram's studies of obedience.
- d.* This describes deindividuation, a phenomenon not examined in Milgram's studies.
10. *c* is the answer. Berkowitz says that the direct cause of most kinds of aggression is negative affect, in other words, a bad mood. (see Aggression)
- a.* By itself, the generalized arousal Luis feels from exercising would not lead to aggression. The arousal must be coupled with an aggressive situation.
- b.* By itself the cue of violence from a TV program is not sufficient to set off aggression. The cue must be combined with stress or perhaps negative affect.
- d.* There is no evidence to suggest that nudity or pornography alone will lead to aggression.
11. *b* is the answer. According to the learning approach, we can learn aggression by watching others' aggressive behavior. The boys may have learned their aggressive behavior from watching violent cartoons. (see Aggression)
- a.* According to the biological viewpoint, aggression is caused by physical factors, not by learning.

- c. According to the frustration-aggression hypothesis, aggression is displayed if a person is frustrated and there are aggressive cues in the environment.
 - d. Instinct theory proposes that aggression is natural, not learned.
12. *b* is the answer. Evolutionary theorists believe that helping behavior increases the chances of survival. Consequently, the chances of one's own genes being passed on increase. (see Altruism and Helping Behavior)
- a, d. A learning theorist would say that people learn helping behaviors because they are rewarded for them.
 - c. According to evolutionary theory, people do not help others for the sake of those individuals but rather to increase the chances of passing on their own genes.
13. *d* is the answer. The greater the number of people present at the scene, the lower the likelihood will be that any one of them will help. (see Altruism and Helping Behavior)
- a. Although our natural curiosity draws us to the scene, this is not the bystander effect.
 - b. People gather, but it is not known whether rescue operations will necessarily be hindered. This does not describe the bystander effect.
 - c. People may be more likely to help when they see others doing so, but this does not describe the bystander effect.
14. *b* is the answer. This is a particular type of resource dilemma involving public goods. In the short run, the individual benefits by watching public television without contributing. But if no one contributes, there will be no revenue to keep this kind of TV on the air. (see Cooperation, Competition, and Conflict)
- a. Advertisers spend money to sponsor a program based on its ratings. This is a business practice; there is no common resource involved.
 - c. This option could be an example of a superordinate goal, but not of a resource dilemma.
 - d. This statement describes potential results of the prisoner's dilemma.
15. *b* is the answer. According to the empathy-altruism theory of helping behavior, if people know what the person in need feels like, they will be more likely to help. (see Altruism and Helping Behavior)
- a. The arousal: cost-reward theory doesn't focus on empathy for the person in need; it focuses on the upset of the helper. If the person is upset enough by the other person's plight, he or she is likely to evaluate the price of helping.
 - c. There is no environmental theory of helping behavior, although population density and noise do influence helping.
 - d. The evolutionary theory states that we are more likely to help relatives. Evolutionary theorists do not take empathy or arousal into account.
16. *a* is the answer. When the tit-for-tat strategy is used, presumably to increase cooperation, competitive maneuvers are punished with competitive maneuvers. (see Cooperation, Competition, and Conflict)
- b. If cooperative moves are punished with competitive moves, cooperation will decrease.
 - c, d. The tit-for-tat strategy involves responses to the other player's move. There are no strategies based on a pattern of cooperation or competition on the part of just one player.
17. *a* is the answer. When superordinate goals are emphasized, people feel like part of the same group, and usually work together better. (see Cooperation, Competition, and Conflict)
- b. Recognizing individual contributions would probably create more competition and conflict.
 - c. Communication generally has a positive impact. Often when people discuss issues further, they can correct misperceptions or attributional errors.
 - d. A contest would most likely increase competition, thereby increasing conflict.
18. *b* is the answer. This is the tendency to attribute behavior to internal dispositions rather than to influences of the situation. Conflict often results from an attributional error. (see Cooperation, Competition, and Conflict)

- a.* This is a strategy used to stimulate cooperation.
 - c.* This is a small-group phenomenon that involves excessive cooperation.
 - d.* This is a technique for managing conflict.
- 19. *b* is the answer. The person-oriented style is characterized by asking group members for their opinions. (see Group Processes)
 - a.* The tit-for-tat method is a competitive strategy, not a leadership style.
 - c.* A task-oriented style is characterized by giving directives without input from the group.
 - d.* You might be thinking of the parenting style discussed elsewhere in the text. While authoritative parenting has similar features, it is not a leadership style.
- 20. *b* is the answer. Small, closely knit groups with strong, opinionated leaders tend to lose the ability to evaluate their decisions realistically. (see Group Processes)
 - a.* Deindividuation is the tendency of people to behave in a less inhibited way when in a crowd.
 - c.* Social loafing is working less hard in a group than when alone. In closely knit groups, social loafing would be reduced because members identify with the group.
 - d.* Social impairment occurs when a person performs more poorly while others are present.

Now turn to the quiz analysis table at the end of this chapter to find which areas you know well and which areas you need to work on. Circle the numbers in the table for items on Quiz 2 that you answered correctly.

For each question you answered correctly, circle its number. (Quiz 1 numbers are not shaded; Quiz 2 numbers are shaded.) Are there patterns in the types of questions or the topics you got wrong that could direct your further study? Did you improve from Quiz 1 to Quiz 2?

PSYCHOLOGY

SIXTH EDITION

Written in a lively, contemporary style, Doug Bernstein and his colleagues deliver a skillful balance of both classical and contemporary topics in this comprehensive, research-oriented text. *Psychology*, Sixth Edition, retains the best features of the previous editions while offering new material to help you succeed in psychology.

New and Updated Features

"Try This" Icons include dozens of new figure and photo captions, and in-text activities that help you understand and remember a psychological principle by demonstrating it yourself.

"Thinking Critically" is the signature five-question approach applied to each chapter to help you analyze information critically.

"Focus on Research" questions emphasize the value of research and the creativity with which it is often conducted. The five-question organization of this feature is designed to help you organize your thinking about research methods and its results.

"Linkages" features help you grasp the many connections among different subfields of psychology and chapters in the book.

Supplements packaged with this text

Succeed in College! is a skills-building booklet containing selected chapters from Walter Pauk's best-selling study skills text *How to Succeed in College*.

PsychStart CD-ROM is a brand-new CD, which contains study guide content to help you study for exams. This consists of The Big Picture (chapter

summary), Chapter Walkthrough (which poses various types of questions to help you build your own detailed chapter summary), What's That? (labeling exercises), Critical Thinking Questions, Practice Tests, and a glossary with pronunciation.

Additional Study Supplements

The **Study Guide** employs numerous techniques—such as detailed chapter outlines, key terms sections, fill-in-the-blank tests, and learning objectives—to help you learn.

The **Student web site** contains additional study aids, such as self-tests and flashcards, as well as activities that ask you to evaluate materials that you find on the web. It also offers multimedia tutorials on topics instructors have identified as the most difficult to teach and the most appropriate for multimedia treatment. These will help you learn difficult concepts by experiencing activities in different media and by being asked to respond interactively. Visit college.hmco.com/psychology/students/.

For more information, please visit Houghton Mifflin's homepage at college.hmco.com.
